IN a long and exhaustive article on the above subject which occupies more than half of the entire space in the *Archives de Médecine Navale* for November and December, 1898 Dr L Chastang, who is a naval surgeon of the first class, gives the following picture of life in a French cod fishing fleet "Over and over again," he exclaims in his exordium "has the miserable existence led by these hapless beings been made public during the last 40 years, but were the writers to be now called upon to report afresh all that they would have to do would be to copy their original reports In this profession there is no such thing as progress" The vessels are strong and speedy, but everything is sacrificed to the cargo the crew being overcrowded to the last degree The filth is simply indescribable The men never take off their clothes and seldom even remove their immense boots when they turn in Washing is unknown Putrescent refuse is habitually thrown under foot As there are no sanitary appliances of any description the calls of Nature are obeyed in every corner not only on deck but below in the sleeping place The sleeping berths are fearful holes absolutely unventilated Everywhere filthiness is pushed to its maximum "Side by side with alcoholism" continues the author, "filthiness is the chief vice of the French sailor, at once the most profound the deepest rooted, and the most hideous to appreciate this properly he must be seen and smelt The observer who has only visited vessels of a similar character but flying flags different from ours could form no idea of it, nor would he see anything approaching it Fortunately the men spend most of their time in the open air They work on an average 18 hours out of the 24, and that without a day off from first to last even on Sundays, throughout the whole of the five or six months during which the fishing lasts In the matter of food there is apparently little cause of complaint, although Dr Chastang seems to think that the men are induced to put up with indifferent eatables by a more than liberal allowance of strong drink In addition to wine, of which a large ration is served out daily, each man receives several drams of so called brandy In reality it is corn spirit of the cheapest quality Living under such extremely insanitary conditions it is a remarkable fact that there is little or no sickness of an acute description among the cod fishers Rheumatism and neuralgia are chiefly complained of, but cases of typhoid fever are also comparatively frequent. There can be no doubt however, but that every one engaged in the industry grows old before his time Men of 40 years of age have the appearance of men of 70 years and it is a pregnant fact that State pensions to North Sea fishermen are few and far between Although they invariably commence as youths they have nearly all died off before the completion of their 25 years service entitling them to a pension Badly as our merchant sailors may think themselves treated we venture to think that from a hygienic and moral point of view no British shipowner can be compared with the *armateurs* who control the lives and fortunes of French fishermen

THE PAY OF COLLIERY SURGEONS

IN our issue of Nov 12th 1898 we mentioned that a movement had been started among colliery surgeons and other practitioners undertaking duties by contract in the county of Durham to obtain better pay On Dec 8th 1898 a meeting was held at Durham to consider the matter The practitioners in the county had previously been notified by circular of the meeting and the motions to be submitted to the meeting had been forwarded to them As a result 70 practitioners attended the meeting, while 300 sent in their adhesion to the motions These, which were carried unanimously, were as follows first, that an association of practitioners in the county of Durham and the neighbourhood should be formed to protect the interests of the profession, to be called the County of Durham Medical Union; and, secondly, that the rate of remuneration to be paid by an adult workman per fortnight should be *9d* instead of as at present *6d*. The reasons given for this increase were set out in our issue of Nov 12th, 1898 Some of those present at the meeting expressed a fear that the result of the resolutions would be to swamp the county with new medical men who would contract at the old rates We hope for the honour of the profession that this will not be the case and we do not think that it will be, for since the action of the General Medical Council in putting down unqualified assistants the supply of medical men is not so much in excess of the demand As an instance of this we know that when one firm of practitioners advertised some five years ago for an assistant they received 50 applications On advertising this year they only received four or five—a fact which presumably shows that the supply of unemployed qualified men is much lessened

VOMITING IN INFANCY

DR G VARIOT contributes to the *Journal de Clinique et de Thérapeutique Infantiles* of Dec 22nd, 1898 and Jan 5th 1899, some excellent observations on the causes and prevention of vomiting in infancy The subject is discussed more particularly in its relation to diet and it is divided for convenience into two sections—(1) vomiting in breast fed infants, (2) vomiting in artificially fed infants The following causes are comprised under the first head a probably toxic action in the milk of weakly mothers, the furtive introduction of other food than breast milk, drugs taken by mothers, the influence of emotion on the breast milk, and (?) an excess of casein in the milk. This last-named factor in the process has been made much of by American practitioners. Dr. Variot thinks too much importance has been attached to it and he strongly condemns the "milk laboratories" by which it is sought to remedy the supposed incapacity of nature as a milk producer. He has one method which he relies upon as a corrective of her temporary errors—namely, the regulated use of sterilised cow's milk. This he does not resort to until a methodical use of the maternal breast under as favourable conditions as are obtainable has failed. We now come to the second head. In the feeding of children brought up by hand the quantity of milk taken during a given time is, Dr. Variot reminds us, of only less importance than its quality. He quotes the researches of Snitkin, Fleischmann, Morgan Rotch, and others in proof of the rapid physiological development of the infant stomach which, beginning with a food capacity equal to 30 grammes at birth, rises to that of 90 grammes from the sixth to the eighth week of life. Nevertheless, as he remarks, its capacity is still limited and a milk-supply of from 60 to 80 grammes is more suitable than the gluttonous dose of 125 grammes which is not an uncommon cause of over-distension and consequent rejection of milk. He advises as the best mode of treatment in such cases a reduction in the amount of milk taken and an extension of the intervals between the meals. In a case of obstinate vomiting quoted by him this plan was adhered to in spite of some temporary loss of weight with almost immediate and lasting benefit and ultimately with much improved nutrition. In this connexion we may again direct attention to Dr. Comby's interesting observations on Dilatation of the Stomach in Infancy, quoted in THE LANCET of July 24th, 1897. Dr. Variot is an undoubting advocate of sterilised milk for hand-fed infants and is fortified in this position by an experience of 500 cases thus nourished at the Belleville Dispensary. He records the interesting fact that the milk is taken undiluted in many instances even by infants a few weeks old and does not disagree. In others a weaker digestion entails necessary dilution by adding a third part of boiled water. The quantity must in like manner be regulated not by mere age, but rather by the body weight and relative robustness of the child, an atrophic infant four months old requiring from 75 to 90 grammes each time when fed, and a healthy child of the same age from 120 to 135 grammes.

THE CAMBRIDGE UNIVERSITY ASSOCIATION.

A WELL-ATTENDED meeting was held on Tuesday afternoon last at Devonshire House on the invitation of the Duke of Devonshire, Chancellor of the University of Cambridge, to consider the pecuniary position of the University. The Cambridge University Association was formed some two years ago to enlarge the resources of the University for educational work by creating an endowment fund, and the meeting over which the Duke of Devonshire presided may be looked upon as its inaugural one. His Grace made an excellent speech advocating the foundation of the Association as a bond between old and new members of the University and gave practical proof of his sentiments by contributing £10,000 towards the endowment fund. The Vice-Chancellor of the University (Dr. Alexander Hill, M.D. Cantab., Master of Downing) proposed and Professor Jebb, M.P., the representative of the University in Parliament, seconded a resolution approving the establishment of the Association; the Master of Trinity (Dr. Butler), Sir Richard Webster, Professor Clifford Allbutt, M.D., and Professor Ewing, spoke forcibly in its support, and it was carried unanimously. An executive committee was then elected. The Duke of Devonshire announced that the firm of Lord Rothschild would contribute £10,000 to the Association and that the Drapers' Company had intimated their intention of contributing for ten years £800 a year in support of a Professorship of Agriculture. A cordial vote of thanks to the Duke of Devonshire for his services was unanimously accorded and in this auspicious way the work of the Cambridge University Association has been inaugurated. Remembering the position which the University has achieved for itself in the paths of science and without any consideration of its claims as a splendid institution of unsullied history, all medical men must wish this successful start to be followed up rapidly.

AN ELOQUENT TRIBUTE.

THE following lines appeared recently in the *Westminster Gazette*. They constitute as eloquent a tribute to the virtues of the medical life as we have ever read:—

TO A CERTAIN DOCTOR.

"I'm *only a doctor*," is your cry.
  "Concerned with the body's ills and maims,
But witless of art and poesy,
  And lost to the spirit's finer aims."

Ay, only a hand by hundreds blest,
  A heart that has ached for all, save self,
A brain racked ever to find them rest,
  A soul whose riches are scorn of pelf.

In vain we argue; the theme is old:
  Some men love horses, some singing-birds
But e'en if the poet's song ring gold,
  Shall deeds that are gold weigh less than words?

You waived the pleasure and wooed the strife,
  Of thorns, not roses, have made your bed;
You longed for the lovely side of life,
  And fought with the terrible instead—

Longed sore, but never had time to give,
  "Till now it is all too late," you say.
So be it. Why, man, the life you live
  Is one long poem from day to day.

JAMES RHOADES.

We trust to hear more and frequently from Mr. Jame Rhoades.

MR. E. CLIMSON GREENWOOD has been appointed teacher of vaccination to the Medical School of St. George's Hospital. Under the provisions of the Vaccination Act the teaching of vaccination at vaccination stations necessarily comes to an end. Under the arrangements now made at the St. George's school the teacher of vaccination will give a short course of lectures in the school and will make arrangements for the students attending the lectures to accompany him during domiciliary visits. One advantage may b expected from the new conditions—viz., that the student will be able to watch the progress of the vaccine vesicle to a later stage than was the case under the old system.

THE annual general meeting of the Hunterian Society will be held on Feb. 8th, at 8 P.M., at the London Institution, Finsbury-circus. At 8.30 P.M. the annual oration will be delivered by Sir Hugh Beevor, Bart., M.D. Lond., on "The Declension of Phthisis." Members of the medical profession are invited to attend. The annual dinner will be held at the Café Monico on Friday, Feb. 10th, at 7 P.M.

DR. F. J. WALDO, medical officer of health of the Temple and Southwark, has been appointed Milroy Lecturer by the Royal College of Physicians of London for the year 1900. The subject of the lectures will be: Summer Diarrhœa with Special Relation to Causation and Prevention.

BRISTOL INFECTIOUS DISEASES HOSPITAL.—At a meeting of the Bristol Sanitary Authority held on Jan. 17th it was decided to recommend the Town Council to appoint Dr. D. S. Davies (the medical officer of health) medical superintendent of the new infectious diseases hospital at a salary of £50 per annum for the first year and £100 afterwards.

QUACKS AND ABORTION:

A CRITICAL AND ANALYTICAL INQUIRY.

VI.[1]

WE have spoken hitherto of the nature of this trade, we have given our views upon the subject and set out the materials upon which those views are based, and we have also expressed an opinion that the advertisements of the trade are likely to appear less frequently in the immediate future, at any rate in those papers which value their reputation. We have shown by the case of the Irristum Company that no newspaper is bound to insert advertisements if, even after making a definite contract to do so, it finds that in fact they are of such a nature as those of the company in question. We have, however, said nothing of the question of the liability of the newspapers to prosecution for inserting such advertisements. It was stated by Mr. Muir at the police-court, before the Chrimes brothers were committed for trial, that steps would in future be taken against newspapers which lent themselves to the advertising of abortifacients. A presentment recommending such a course has been made by the jury in the Chrimes case and Mr. Justice Hawkins's last act as a judge was presumably the forwarding of this recommendation to the proper quarter after the trial was concluded.[1] Mr. Muir presumably represented the City Police alone, while the Home Office or the Treasury, or whatever office may have initiative power in such matters, has viewed the advertisements to which we have called attention in detail, and scores of others as bad, for long with indifference. At the same time it is possible that steps to prosecute may now be taken. If they are not there is considerable likelihood of things very soon relapsing into their former condition. We said when we commenced our articles that the advertisements were less common than they had been in October; at the same time we find exactly as we predicted that they have not really ceased. The long columns of puffery, innuendo, and dirt appear temporarily to be without a journalistic lodging; but a line or two has made an appearance in several provincial prints since the exposures which shows that the evil is not dead, but only sleeping. This makes us sure that when once the popular outcry against them has been hushed the less scrupulous proprietors or managers will again yield to temptation unless care is taken to see that they do not prostitute their advertisement columns in this way.

With regard, however, to the precise legal position. Those who publish that which is obscene can undoubtedly be indicted for so doing and the test of obscenity was laid down by Lord Chief Justice Cockburn in 1868 in an appeal by a person of respectable position who from motives of Protestant propagandism disseminated copies of "The Confessional Unmasked." That test is "whether the tendency of the matter charged as obscenity is to deprave and corrupt those whose minds are open to such immoral influences and into whose hands a publication of this sort may fall." Even if the ultimate object in view is to do good it will not avail him who publishes in such circumstances and no one can say that there is such an object in the advertising of the specifics we have analysed. It seems, however, likely that owing to their not being on the face of them indecent they have never been treated as obscene libels by the police or anyone else. The veil of pretended cures for amenorrhœa has protected them. It is, however, possible that the prosecution, if undertaken, would be for inciting, being accessories before the fact, to the criminal acts of which individual advertisers may be guilty as principals—a far more serious charge—or for inciting to commit a felony. If any such proceedings were made retrospective by being taken against those papers publishing such advertisements before the case of the Chrimes brothers threw lurid light on the subject the courts would be fully occupied for some time to come, while the "Irristum" case referred to already would make it a little difficult for some of the accused to plead ignorance of the nature of the advertisements in defence.

There is one more point arising out of the legal aspect of the case to which we call attention. From all, or nearly all, newspapers advertisements such as those of Thomas Ottey and "Professor" Leslie have, for the time at any rate, disappeared. We notice, however, that there still are published in them a number of notices which come within the definition of indecent advertisements given by a recent Act of Parliament known as the Indecent Advertisements Act, 1889. It is a statute which is not quite so comprehensive as its title would imply, for it only prescribes penalties for the affixing of indecent advertisements in public places, the distributing then as handbills and other similar methods of making them public, while it has been held not to apply to newspapers. We quote the 5th Section of this Act: "Any advertisement relating to syphilis, gonorrhœa, nervous debility, or other complaint or infirmity arising from, or relating to, sexual intercourse shall be deemed to be printed or written matter of an indecent nature within the meaning of Section 3 of this Act,[2] if such advertisement is affixed to or inscribed on any house, building, wall, hoarding, gate, fence, pillar, post, board, tree, or other thing whatsoever so as to be visible to a person being in, or passing along, any street, public highway, or footpath, or is affixed to, or inscribed on, any public urinal, or is delivered, or attempted to be delivered, to any person being in, or passing along, any street, public highway, or footpath." The advertisements described in this section are precisely those which, we have said, are still published in those papers which have given up advertising abortifacients and we have two observations to make with regard to this Firstly, we submit that no proprietor of a public newspaper with any sense of propriety or with any self-respect would allow in his paper matter which is by law declared to be indecent and punishable as such if found in a public latrine. Secondly, we wish to point out that those who pay for the insertion of these advertisements are not only of the same class, but are in many instances the same persons as those who sell pretended abortifacients in the guise of emmenagogues. These advertisements are therefore likely to become a means of bringing the abortionist into contact with his clients, for, as we have shown, when a quack sends his medicine to those who order it, he always sends a sheaf of advertisements of all the other articles and concoctions of a kindred nature which form his stock-in-trade. It may also be observed that although the section quoted only says that the advertisements it refers to shall be deemed indecent on a gate-post or urinal, or in other certain circumstances, it by no means follows that such advertisements, if flagrantly plain-spoken or unusually suggestive, may not be found by a jury to be indecent when appearing in a newspaper, and therefore to those whose sense of decency is not fine enough to lead them to exclude such stuff we suggest that there may be danger in it of legal penalties. We shall watch with interest during the next few months the columns of newspapers which have derived profit hitherto from the advertisements of pretended abortifacients, aphrodisiacs, and remedies for venereal disease. We are inclined to believe that the improvement now observable will be but short-lived unless the police in London and in the country show less indifference than heretofore.

With regard to the results of the examination in our laboratory of the potions and pills advertised by the different quacks it will be observed that, despite the fact that no definite line of action or scheme of analysis can be laid down for the identification of vegetable extracts or substances by chemical tests, we have been able nevertheless to state—and state for practical purposes exhaustively—the nature of the contents of both orders of nostrum. We hope to deal shortly with the question of the limitations of chemical analysis in this connexion—i.e., in its application to the identification of drugs in medicines, pills, and potions. We now wish to record that, so far as successful identification has been achieved in the series of articles which we are concluding, it has been due largely to tests of comparison instituted with reference to known specimens which were most kindly placed at our disposal by Messrs. Burroughs, Wellcome, and Co. We cordially tender our thanks to these gentlemen. Some of the preparations, known specimens of which we were compelled to have at our disposal, do not occur in the ordinary stock of manufacturing chemists, but in spite of this Messrs. Burroughs, Wellcome and Co. were good enough to procure them—an act of courtesy which has very materially assisted our laboratory staff in the work of unravelling the secrets of the abortion-monger.

---

[1] Articles I., II., III., IV., and V. were published in THE LANCET of Dec. 10th, 17th, 24th, and 31st, 1898, and Jan. 21st, 1899, respectively.

[2] [illegible]

felt as high up the river as Molesey Weir. The Conservators are therefore confirmed in their opinion that the water in the river should not be reduced to a less volume than 200,000,000 gallons daily. The amount of water which passes down the Thames throughout the year taken as a whole is sufficient to meet the wants of the water companies if storage reservoirs of sufficient size existed to take it. The witness insisted that in his opinion it was of vital importance that a flow of 200,000,000 gallons a day should pass down the river at Teddington.

Colonel LOCKWOOD, M.P., in answer to the Chairman, admitted that the East London Company had failed to give an adequate supply to their customers during last autumn and on some previous occasions. They had not, however, entirely ceased to give a supply; "they did not put up their shutters."

The CHAIRMAN remarked that they put them half up and that it was clear that in a year like 1898 or even in an ordinary year the resources of the company were at present inadequate. The witness admitted that this was the case. He, however, gave it as his opinion that much of the inconvenience which had been experienced by the customers of the company last year was due to the removal of the cisterns.

The CHAIRMAN pointed out that evidence had been given before them that the cisterns were full of mice and mud. The witness said that the company refused to supply new houses which were not furnished with cisterns, but after the first supplies were given the cisterns sometimes disappeared. He was of opinion that a great deal of wilful waste had taken place in their district, and that some of their customers wasted as much water as they could to spite the company. With regard to the purchase of the companies' undertakings the witness said that they did not wish to sell. He did not think the London County Council would be able to manage the undertakings as well as they were at present managed, and they had misled the ratepayers as to the expediency of purchase. Should purchase, however, be decided upon, the witness said that, in his opinion, the scheme of purchase which had been put forward by Mr. Banbury was the best method of dealing with the matter. If this scheme were not adopted purchase should take place under the Lands Clauses Act. His reasons for favouring purchase under this Act were (1) because it was the recognised law of the land for the sale of such undertakings; (2) because it provided recognised and well-considered machinery for assessing the value of the property; (3) because all its provisions had been contested before judges and the various points settled; and (4) because wherever a corporation had compelled a water company to sell this Act had always been the one adopted.

The forty-eighth sitting of the Royal Commission was held at the Guildhall, Westminster, on Jan. 31st.

THE INFLUENCE OF SCHOOLS IN ACCENTUATING THE SPREAD OF CERTAIN INFECTIOUS DISEASES.

III.

THE evidence to which we referred in our last two articles, published on Jan. 21st and Jan. 28th, went to show the manner in which elementary schools are apt to act as diffusers of infectious disease, and how that, although this is not by any means always the case when diphtheria is prevalent, the effects of their influence in the mass can frequently be brought out when the figures dealt with are sufficiently large and far-reaching. In this, our concluding article, we shall inquire how this influence for harm which schools are liable to exert may be best detected and controlled.

It is clear in dealing with a matter of this nature that unless there is a thoroughly well-organised intelligence department much of the energy expended on attempts at control will be more or less aimless or ill-directed. If we are to detect the earliest indications of any given school being a factor for harm we must know, as far as practicable, the exact arrangement which obtains at such school, the composition of the several departments, and the circumstances under which the children therein are liable to meet together, as, for instance, in their playgrounds or through the medium of sanitary conveniences common to girls and infants. We should also have a good general idea of the area from which the school draws its children and of the opportunities of aggregation which are afforded for the children at places other than in the secular schools. This will involve *to some extent a knowledge of the habits of the district and of the arrangements made for religious instruction on Sundays.*

But, however intimate knowledge of the habits of the people may be, the machinery of control will assuredly tend to break down unless one essential factor, it may be called the lubricating factor, is present. By this is meant a cordial coöperation between the sanitary authorities and the school authorities. If there be friction in this particular and personal questions are allowed to weigh unduly, all our efforts are likely to be frustrated.

In the forefront of our measures must be as nearly as possible complete information of all cases, slight as well as severe, of the current malady. Without this no accurate knowledge can be obtained of the distribution of any given disease and of its proper relations to the scholars of any particular school. A well-carried-out system of ascertaining all facts as to sickness, coupled where possible with a record of the facts so far as they concern the current malady on a spot map of a district, is of infinite value; and if on such a map there can be roughly indicated what may be termed the "sphere of influence" of each school, it will much facilitate the early detection of disease prevalence in relation to any given school. Information such as this will enable the medical officer of health to watch the development of events and to furnish the school authorities with the necessary information as to the exclusion of scholars from invaded houses, &c. It would tend to assist matters if the medical officer of health were furnished with the names and addresses of children attending each school in his district, such a list being of course corrected periodically. Under any circumstances this official should be placed by statute in such a position as to enable him to procure this list should he deem it desirable. It is clearly inexpedient in the interests both of the lives of children, and of education, that the experiences of Mr. Harris, the medical officer of health of Islington, should be repeated. This gentleman was refused by the London School Board the information above referred to in spite of the fact that Mr. Harris's object was to ascertain by inquiry at the houses of the school-children to what extent measles was still prevalent amongst the scholars. Unfortunately for the intelligence department measles is not notifiable and hence Mr. Harris was almost entirely dependent upon the School Board for assistance. Valuable, however, as is the information to be derived from compulsory notification the mistake must not be made of assuming that it tells us everything. Notification looked at broadly must be understood as meaning only that certain cases of infectious disease have been diagnosed by medical men. It leaves untouched all those cases concerning which no medical man has been consulted and all those about which the medical adviser has not yet made up his mind. To assume that notification is a complete measure of the prevalence of infectious disease is to assume that a medical man is always called in in cases of mild illness and, moreover, that he is always correct in his diagnosis. Notified cases must be regarded as merely an index, and a very rough one, of the actual facts, and search must be made for the existence of non-recognised cases in the neighbourhood of those already notified. Search in this sense may be made in more than one direction, but probably the examination of school-children in school is the plan likely to yield advantageous results with a minimum of labour. This examination to be of the greatest value should be made by a medical man well versed in the initial and late signs of infectious disease, but where this is not feasible the master or mistress may afford very great assistance by an intelligent coöperation with the medical officer of health, who should, of course, always be informed of the exclusion from school of any child owing to a suspicion of infectious disease. Doubtless the best officer to make an examination of the school-children is the district medical officer of health. He has the distribution of notifiable diseases at his finger ends, and he is thus well fitted to gauge at their proper value the facts which come under his notice. We are fully aware that at present the medical officer of health has no statutory right to examine the school-children, and we are further aware that a certain medical officer of health in London who attempted such an examination is reported to have been "severely censured" by the London School Board, who observed that they would not allow him "or any other medical officer of health to examine children in their schools." Other school boards have, too, we believe, taken up a similar attitude. But all this is simply an additional reason for affording the medical officer of health a statutory position as regards this matter both in the board schools and in the voluntary schools. In addition to information to be derived by the assistance of the teachers in our elementary schools we must look to the school attendance officers for their coöperation, and it would probably be useful if these officers were furnished with stamped forms upon which they might notify suspected cases of infectious disease to the medical officer of health and to the school authorities, and also with leaflets of advice which they might leave at invaded houses. So, too, greater use might be made of such persons as the registrar, the clergy, district visitors, &c. With regard to the clergy, their coöperation should be sought in all matters connected with the Sunday-school and although we think that statutory powers should be conferred upon sanitary authorities to close these schools when necessary we feel sure that the clergy will always do their best to assist health administration. Into the subject of disinfection we have no space to enter here. Clearly all houses in which cases of infectious disease, be it small-pox or measles, have been discovered by whatever means should be carefully disinfected, and no children from such houses should be allowed to return to school without a medical certificate to the effect that danger of infection has passed. We fear, however, that this very elementary precaution is but too frequently disregarded.

A word in conclusion as to the sanitary condition of our elementary schools. We have at times found that the officers of local sanitary authorities have been under an impression that these institutions were outside their province and that hence they were not at liberty to search therein for nuisances. As a result of this inaction the closets in connexion with schools, more especially in rural districts, may at times be found in a condition which is far from wholesome and which would not improbably have a tendency to foster enteric fever and diarrhœa, if not other diseases of this class.

THE PURIFICATION OF RIVER-WATER FOR DRINKING AND INDUSTRIAL PURPOSES.

AN exceedingly instructive and important contribution on the subject of water-supply has recently been published in the form of a report on an investigation made at the instance of the President and directors of the Louisville Water Company by Mr. George W Fuller who is well known as having assisted in some excellent work on the question of biological purification of sewage in connexion with the administrative work of the State Board of Health of Massachusetts. The report has been published in the form of a book which must be regarded as a valuable volume of reference considering the remarkable precision and thoroughness of detail observed during the course of the experimental inquiry[1] In short, it is a stupendous piece of work, the report containing thousands of practical and experimental results relating to filtration, sedimentation, coagulation, and the degree of efficiency of the purifying processes investigated. The report occupies a large volume of 480 pages The work was begun on Oct. 1st, 1895, and was practically finished by August, 1897. The inquiry deals of course with the special circumstances of the case under consideration—that of the Ohio River—but the particular conditions therein encountered obtain also elsewhere, and there can be little doubt that the results of this particular experience will be very generally applicable to the great river water-supplies of the world.

As we have said, this investigation relates to the purification of the water of the Ohio River which is supplied to the towns on its banks The watershed of the Ohio River above Louisville is about 85,000 square miles in area. This area includes portions of the States of New York, Pennsylvania, Ohio, Indiana, North Carolina, Virginia, West Virginia, and Kentucky. As might be expected, very wide extremes in geological formation exist in this large watershed, in consequence of which, together with other factors, wide and rapidly changing variations in the composition of the river water are produced. The population resident in this large watershed is about four and a half millions. A peculiar difficulty has to be faced in the purification of Ohio river water on account of the occurrence of suspended mud silt and clay, which practically preclude filtration being adopted alone as a method of purification. These characteristics make Ohio river water a difficult and expensive water to purify. Indeed, owing to the fact that at times this river water contains large amounts of exceedingly minute clay particles subsidence alone is of no avail, and if purification is to be successful and economical the use of a coagulation method is absolutely imperative. In the case of the Ohio river water all three methods—subsidence, coagulation, and filtration—would appear to be correct in principle and the experiments relate to the conditions which were found most suitable for the purification of this water and to the methods which were found to give satisfactory results in accordance with the demands necessitated by these conditions. The most suitable coagulant found for the treatment of Ohio river water was sulphate of alumina. Persulphate of iron, though slightly cheaper, lacked some of the decided advantages of sulphate of alumina. The electrolytic production of aluminium hydrate from metallic aluminium electrodes was found impracticable both on the grounds of excessive cost and of irregularities in efficiency. With regard to the electrolytic production of iron hydrate from iron electrodes this process yields a satisfactory coagulant up to the equivalent of three grains per gallon of sulphate of alumina. But occasionally the amount of dissolved oxygen in the water is inadequate to oxidise larger quantities than this equivalent. Having regard, however, to the cost and the limitations in the amount which can be safely applied without the presence of iron in the effluent as well as to certain irregularities upon reversing the direction of the electric current this process was deemed not advisable in the present instance. Concerning the Anderson process for the preparation of iron hydrate directly from metallic iron the results of laboratory tests indicated that it was not applicable for the economic and efficient purification of the Ohio river water. Several other chemical precipitants were tried but only sulphate of alumina was found practicable. One of the chief difficulties in employing this coagulant is the regulation of the quantity of the added chemical to known volumes of the water which is constantly exhibiting variations in composition at different seasons. The scope of requirement in this regard can only be determined by experience, but it is believed by the application of a good system and by great care and close attention it would become practicable to confine the application of coagulants to a range of three or four points; but, as we have said, this can only be gauged by experience under conditions of successful practice. An excess of coagulant is, of course, to be deprecated, the chemical salt passing into the public supply. This would be detrimental to machinery and also would make the water objectionable for domestic purposes. On the other hand, an insufficiency of coagulant would leave the purifying process incomplete.

The quality of Ohio River water after purification by coagulation and filtration, preceded by subsidence as far as practicable, would appear to leave little to be desired. The effluent so obtained is practically sterile. It is bright and good to the taste. It is recommended, however, that to provide against the growth of algæ all sunny environment should be cut off by storing the filtered water in covered reservoirs. The filtered water it is stated would not give any trouble in the case of lead pipes or in iron pipes which are properly coated with protective paints. In uncoated iron vessels the corrosive action would be somewhat greater than in the case of river water owing principally to the removal of suspended matters which in a measure act as a protective coating. With regard to use in steam boilers there would be more incrusting constituents than in the river water although the annual average amount in the filtered water would be only approximately 60 per cent. of the quantity normally present in the river [illegible] during flood seasons. The effect of this addition, [illegible] neutralised by the removal of the [illegible] with the waters of oth[illegible] water for steam

---

[1] Report on the Investigations into the Purification of the Ohio River Water at Louisville, Kentucky, made by George W. Fuller, Chief Chemist and Bacteriologist to the Louisville Water Company. Pp. 480 and 8 full page plates. Price $10.00 net. New York: D. Van Nostrand Co.

The final conclusion of this admirable and colossal piece of work is that the general method of subsidence, coagulation, and filtration is applicable to the satisfactory purification of the Ohio river water at Louisville. The Warren, Jewell, and Western systems of conducting the process do not, however, appear to afford the satisfactory application of the principle on the large scale. By removing the suspended matters from the water, however, large reductions could be made in the size of the filtering plant, the amount of coagulant, and the cost of operation. It is estimated that on the basis of 25,000,000 gallons daily these reductions when capitalised at 5 per cent. would represent about 700,000 dollars. Probably for a less sum satisfactory provisions for subsidence as outlined in the report could be provided "which would not only aid in furnishing a filtered water of better quality but would also give the water consumers a better service in other regards."

The report contains an enormous number of experimental results, mechanical, chemical, and biological, which are embodied in a very remarkable series of tables. The water company and all concerned are to be congratulated on the masterly way in which Mr. Fuller, their chief chemist and bacteriologist, has attacked the problem which has been presented to him. It must have been an enormous undertaking and a very protracted inquiry. It is a model of diligence and enterprise undertaken on behalf of the public interest which might well be followed in this country. We are sure, however, that this very important contribution to the vital question of the purity of public water supplies will not fail to convey many valuable lessons to those entrusted with the details of water administration at home.

REPORT OF THE SANITARY MEASURES IN INDIA IN 1896-97.

THIS is one of the reports periodically issued by the India Office and was published in December, 1898, for the information of both Houses of Parliament. It contains chapters on the health of the European and native troops, and on the health of prisoners in jails and of the general population of India; it also contains chapters on vaccination, on medical institutions, including medical schools and lunatic asylums, and a chapter on sanitary work in that country. Appended to it are abstracts of reports by the three principal sanitary commissioners in India, and memoranda by the Army Sanitary Commission thereon.

Nearly 40 pages are first of all taken up with an introductory report prepared in the India Office of this country. Attention may be fairly called to this as an admirable sample of what may be termed *précis* writing—a much more difficult and laborious task than it is commonly believed to be; for as a matter of fact it is not by any means always easy to sacrifice redundant or irrevalent matter and to epitomise and arrange what remains so as to omit nothing of practical value and at the same time present the reader with a lucid statement of what is really essential to be known. This prefatory statement summarises the results furnished by the various Indian officials in their several reports and gives a brief and instructive medical history of the European and native population, together with a record of the progress of hygiene in that country. We have already touched upon many subjects embodied in this official publication when dealing with the reports of the Sanitary Commissioner with the Government of India, but we may nevertheless advert to a few points. In the first place, then, considering the importance of sanitation in India, we are glad to see that Surgeon-General Harvey, the Director-General of the Indian Medical Department, in his evidence before the Plague Commission recently, expressed himself very decidedly as to the benefit which would accrue to India by the appointment of a sufficient number of health officers with good qualifications, whose time could be given entirely to sanitary work. We have so frequently referred to this subject and to the importance of providing a new and improved machinery for this purpose that there is no need to dwell upon it now. Taking a disease like plague, for example, it would, we think, be futile to rely entirely upon inoculation, even supposing its protective power against attacks of that disease to become demonstrably established, for coping with an epidemic or outbreak. We agree with Surgeon-General Harvey that the natives of India would not consent to be inoculated on any large scale in anticipation of an outbreak, and until we know more about the nature and length of time over which the conferred immunity lasts we have grave doubts as to the practicability of applying this method with the object in view. Valuable as it may be, Surgeon-General Harvey is no doubt correct in saying that inoculation cannot be regarded as anything but an auxiliary to sanitary measures. The great obstacle to the introduction and application of such measures on any commensurate scale into India is the enormous expense and the extreme poverty of the native population. Apart even from the ignorance and the conservatism and caste prejudices of the natives the cost of sanitation in India on any scale at all parallel to that in this country would be altogether prohibitive. Still the time has come in our opinion for remodelling our public health system in India with the view of making its application more systematic, direct, and prompt.

Reverting, however, to the report under review we find that as regards the European army Bengal has of the four commands the highest daily sick- and death-rates. The Madras command is the healthiest and its death-rate is not much more than half that of Bengal. 54 per cent. of the total sickness in the European army in India results from venereal diseases and ague. The chief cause of mortality is enteric fever, to which 43 per cent. of the total deaths were attributable in 1896. The death-rate from this fever among the native troops, on the other hand, is only 0·04 per 1000, as against 6·31 per 1000 among European troops. Under a short-service system there is a greater supply of susceptible material and this, of course, means an increased prevalence of the fever in question. Notwithstanding all the efforts which have been made in India to discover and to check its causes it must be confessed that the practical outcome of our efforts is very disappointing. What is a serious feature in the matter is the fact that the hill stations which are the sanatoria and health-resorts of the country have been seriously and [illegible] by affected with this scourge. At page 57 of [illegible] this interesting table is given of various hill st[illegible] in death-ratios of enteric fever in them resp[illegible] common belief, and probably a well-found[illegible] one, that this fever tends to increase with length of occupation. In the case of most of these stations bad years have occurred at more or less irregular intervals, but for some time past, in the case of Dagshai, Subathu, and Cherat, the bad years have been very close together. Special investigations, we are told, have been made into the sanitary conditions of those stations and generally suspicion has been thrown upon the water-supply.

As illustrative of the altered condition of the European force in India as regards married soldiers we may call attention to the table at page 63 which shows that the average annual strength of children from 1886 to 1895 was 59,695, whereas in 1896 it had fallen to 5790. The death-rate per 1000 among children, it may be mentioned, is very high and has decreased but slightly, being 45·60 per 1000 in 1896, as against 46·72 per 1000 for the period 1886–95.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia was held on Jan. 26th, Sir SAMUEL WILKS, Bart., President, being in the chair.

The following gentlemen were admitted Members of the College: Dr. Henry John Davis, Dr. Francis Edward Fremantle, Dr. Thomas Jeeves Horder, Dr. Laurence Christopher Panting, Dr. Sidney Herbert Perry, Dr. Reginald Pratt, and Dr. George Edward Rennie. Licences were granted to 122 gentlemen who had passed the required examinations and several Diplomas in Public Health were granted conjointly with the Royal College of Surgeons.

The PRESIDENT announced that the Swiney Prize for the best work on jurisprudence, which is given every five years, has this year been awarded to Dr. Dixon Mann for his work on Medical Jurisprudence. He also drew attention to a photograph of the portrait of Dr. Chambers, the original having been painted by Holbein. The photograph had been obtained through the kindness of Mr. Dodson of the British Museum, to whom the thanks of the College were tendered. The name of Dr. Chambers stands first on the roll of the College.

The Bissett Hawkins medal for investigations in hygiene was exhibited "On one side is an excellent likeness of the founder, whilst on the reverse is a representation of Æsculapius and Hercules, with the motto, "Ob sedulo cultam medicinæ civilis disciplinam."

Several communications addressed to the College were received, amongst which were the following :—

From the Secretary of the Royal College of Surgeons of England, respecting proceedings of their Council on Dec 8th, 1898, and Jan 12th, 1899

From the Queensland Public Library, thanking the College for a gift of books

From Sir Hermann Weber commemorating by a gift to the College the renewal of his diploma after 50 years by the University of Bonn The PRESIDENT proposed a vote of thanks to the donor, which was unanimously adopted, and Sir DYCE DUCKWORTH (the treasurer) announced that the gift would be placed to the College Endowment Fund.

From the President of the General Medical Council, asking the opinion of the College on a proposal of the Council to obtain additional penal powers, and submitting clauses for amending the Medical Acts with that view There were two propositions—(1) That if a medical man be deemed guilty of any offence that might cause him to have his name erased from the Medical Register the Council should have the power of erasing his name for a limited period, and that afterwards under certain circumstances his name might be returned to the Register ; (2) that as long as the erasion remained in force he should *ipso facto* be deprived of all his medical diplomas The PRESIDENT considered the second proposal so serious that counsel's opinion had been taken to the effect that the College should not give their consent to the proposal Dr LIVEING (Registrar) proposed and Sir DYCE DUCKWORTH seconded a resolution to the effect that the first proposition of the General Medical Council should be approved of by the College, whilst the second should not This was adopted

From the Chairman of the Education Committee of the General Medical Council, seeking information as to the desirability of raising the standard of preliminary education for medical students to that of the senior local and higher grade examinations On the proposition by Dr. LIVEING, seconded by Sir DYCE DUCKWORTH, the consideration of the matter was referred to the Committee of Management.

From the Secretary of the Seamen's Hospital Society on behalf of the General Committee, having reference to the School of Tropical Medicine with printed correspondence It was resolved on a motion proposed by Dr LIVEING, seconded by Dr DICKINSON, that the correspondence should lie on the table

Communications were received from two Members resigning their Membership.

Dr Thorowgood, Dr Bradbury, Sir John Williams, and Dr. Stephen Mackenzie were elected Councillors, Dr. Norman Moore was elected a member of the Library Committee, Professor Clifford Allbutt was appointed an Examiner in Medicine, and Dr J F Payne was elected Librarian

The revised report of the Leprosy Committee was accepted (see THE LANCET, Dec 10th, 1898, p 1572) on the proposition of Sir WILLIAM GOWERS, seconded by Dr CURNOW A report was received, dated December 1st, from the representative of the College on the General Medical Council

The annual and quarterly reports of the Finance Committee were received and adopted A report, dated Dec 12th, was received from the Committee of Management in reference to the instruction in chemistry, physics, practical chemistry, and biology The Committee had decided "that after receiving the written opinion of the several medical schools, the Committee of Management recommend to the Royal Colleges that in Clause 3 on page 4 of the Regulations the words between the brackets be omitted The clause will then be the same as before the alteration "

It was proposed by Dr NORMAN MOORE and seconded by Dr CURNOW that the report be adopted

Dr WASHBOURN proposed and Dr STARLING seconded an amendment, "that the report be referred back to the Committee of Management "

In the discussion which followed Dr ISAMBARD OWEN, Dr F J SMITH, Dr CALVERT, Dr L E SHAW, and Dr. H J CAMPBELL took part.

The PRESIDENT having put the amendment it was declared lost by 10 to 23 The original proposition was then put and carried by a large majority.

After some further routine business the President dissolved the Comitia.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6762 births and 3716 deaths were registered during the week ending Jan. 28th The annual rate of mortality in these towns, which had declined in the three preceding weeks from 19 1 to 18 2 per 1000, further declined last week to 17 0 In London the rate of mortality was 15 8 per 1000, while it averaged 17 7 in the 32 provincial towns The lowest death rates in these towns were 12 0 in West Ham, 12 9 in Cardiff, 13 5 in Croydon, and 14 4 in Halifax ; the highest rates were 22 2 in Sunderland, 22 6 in Preston, 23 3 in Liverpool, and 23 8 in Plymouth The 3716 deaths in these towns included 329 which were referred to the principal zymotic diseases, against 352 and 380 in the two preceding weeks ; of these, 84 resulted from whooping-cough, 71 from diphtheria, 67 from measles, 40 from "fever" (principally enteric), 37 from scarlet fever, and 28 from diarrhœa No death from any of these diseases occurred last week in Plymouth , in the other towns they caused the lowest death rates in Preston, Derby, Wolverhampton, and Oldham, and the highest rates in Salford, Gateshead, Halifax, Sunderland, and Nottingham. The greatest mortality from measles occurred in Nottingham, Bolton, and Manchester, from scarlet fever in Gateshead ; from whooping cough in Huddersfield, Bristol, Halifax, Croydon, Birkenhead, and Sunderland , and from "fever" in Halifax The 71 deaths from diphtheria included 31 in London, eight in Leeds, six in Sheffield, four in Liverpool, four in Hull, three in West Ham, three in Swansea, and three in Leicester. No fatal case of small pox was registered last week in any of the 33 large towns, and no small pox patients were under treatment in any of the Metropolitan Asylum Hospitals on Saturday last, Jan. 28th The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2679, against numbers declining from 2939 to 2749 on the four preceding Saturdays ; 220 new cases were admitted during the week, against 291, 220, and 249 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 363 and 295 in the two preceding weeks, further declined last week to 266 and were 314 below the corrected average The causes of 54, or 1 5 per cent , of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Portsmouth, Cardiff, Bolton, Newcastle-upon Tyne, and in ten other smaller towns ; the largest proportions of uncertified deaths were registered in West Ham, Leicester, Nottingham, Burnley, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21 7 and 21 3 per 1000 in the two preceding weeks, rose again to 22 1 during the week ending Jan 28th, and exceeded by 5 1 per 1000 the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 18 3 in Paisley and 20 2 in Edinburgh to 23 9 in Greenock and 24 9 in Leith The 676 deaths in these towns included 30 which were referred to whooping cough, 15 to measles, 14 to scarlet fever, nine to diphtheria, five to "fever," and five to diarrhœa In all, 78 deaths resulted from these principal zymotic diseases, against 88 and 94 in the two preceding weeks These 78 deaths were equal to an annual rate of 2 6 per 1000, which was 1 1 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of whooping-cough, which had been 35 and 34 in the two preceding weeks, further declined to 30 last week, of which 12 occurred in Glasgow, nine in Edinburgh, and four in Dundee The 15 deaths referred to measles showed a decline of four from the number in the preceding week, and included seven in Glasgow, four [illegible] three in Aberdeen. The fatal cases [illegible] declined from 13 to six in the [illegible] to 14 [illegible]k, of [illegible] in [illegible]

The nine deaths from diphtheria corresponded with the number in the preceding week, and included four in Glasgow and two in Leith. Of the five fatal cases of "fever" two occurred in Edinburgh and two in Leith. The deaths referred to diseases of the respiratory organs in these towns, which had been 156 and 153 in the two preceding weeks, rose to 161 last week, and were 69 above the number in the corresponding period of last year. The causes of 31, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 26·7 to 28·6 per 1000, declined again to 24·9 during the week ending Jan. 28th. During the past four weeks the rate of mortality has averaged 26·8 per 1000, the rate during the same period being 17·5 in London and 23·1 in Edinburgh. The 167 deaths registered in Dublin during the week under notice showed a decline of 25 from the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 10 in each of the two preceding weeks; of these, five resulted from whooping-cough, five from "fever," and one from scarlet fever, but not one from small-pox, measles, diphtheria, or diarrhœa. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·4 in London and 3·3 in Edinburgh. The fatal cases of whooping-cough, which had been three and four in the two preceding weeks, further rose to five last week. The deaths referred to different forms of "fever," which had been one and three in the two preceding weeks, further increased to five last week. The mortality from scarlet fever corresponded with that recorded in the preceding week. The 167 deaths in Dublin last week included 21 of infants under one year of age and 30 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a marked decline from the numbers recorded in the preceding week. 11 inquest cases and 10 deaths from violence were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of eight, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

FLEET SURGEON MICHAEL JOSEPH MCCARTHY has been placed on the retired list of his rank at his own request.

The following appointments are announced:—Staff Surgeons: H. W. Macnamara to Chatham Hospital; and J. L. Barrington to the *Boscawen*. Surgeons: C. J. E. Cock to the *Revenge*; W. J. Codrington to the *Raleigh*; and W. R. Knightley to the *Excellent*.

ROYAL ARMY MEDICAL CORPS.

The under-mentioned Lieutenants are seconded for service with the Egyptian Army: S. L. Cummins and H. G. F. Stallard. Majors H. H. Johnston, C. E. Nichol, and T. Daly, and Captain G. S. Crawford have arrived home from India in the transport *Simla*.

THE COMPETITIVE EXAMINATION FOR WOOLWICH AND SANDHURST.

The *Fortnightly Review* for last month contains a trenchant criticism on the system of competitive examinations as carried out at the present time for candidates for army commissions. The subject is discussed in its physical, educational, moral, and social bearings, and the writer has a good deal to say with which most people will agree, but we are afraid that the constructive part of his article will be found to contain much that is impracticable. The paper is well worth reading and a good many parents at any rate will heartily concur with its spirit. It is no doubt true that the present system of training of young candidates for army appointments violates many of the best-established principles of the laws of health; that the course of preparatory study is, educationally speaking, unsound; that the future prospects in life of the large mass of unsuccessful candidates are injuriously affected because it is often too late for the failures to take up and be trained for another career; that the life of "grind" for the army is far from being the ideal one for a growing lad; and that the long hours of study and anxiety to succeed takes a good deal out of the freshness and brightness of life and with a good many of them only leaves behind a thorough distaste for books. The tests for purely mental qualifications in these examinations are overdone. We have always contended that a competitive examination should be competitive all round and that there should be some physical tests, so that the possessor of superior physical qualities should reap the benefit of them in the shape of marks. We consequently agree with the views of the writer in the *Fortnightly Review* in this respect which he fortifies by a reference to Mr. Francis Galton's papers on the subject. The difficulty, however, is how to apply the principle in practice.

THE UGANDA HONOURS.

The military operations in the Uganda Protectorate have been of an exceptionally trying nature and the officers who have taken part in them well deserve their honours. In the "Papers Relating to Recent Events in the Uganda Protectorate" which have been recently published it will be found that Captain G. S. McLoughlin, R.A.M.C., is specially commended for his services and that the gallantry and great devotion to duty displayed by Captain J. D. Ferguson, R.A.M.C., are fully recognised.

DEATHS IN THE SERVICES.

Staff Surgeon Henry Stewart Jackson, at his residence, Royal Naval Hospital, Chatham, on Jan. 23rd, at the age of 41 years. He studied at Trinity College, Dublin, and the Royal College of Surgeons in Ireland, subsequently taking his Fellowship degree. He entered the Navy as Surgeon in 1882 and was promoted to the rank of Staff Surgeon in 1894.

Deputy Inspector-General Mark A. Harte, aged 59 years. He joined the service in 1861, became Staff Surgeon in 1875, and Fleet Surgeon in 1882. He retired in 1893.

VENEREAL DISEASE AND THE ARMY IN INDIA.

By a general order recently issued by the Commander-in-Chief in India medical inspection of British soldiers serving in India for the purpose of detecting and checking the spread of contagious disease is to be made and punishment enforced for concealment of such disease. Inspection will take place from time to time without warning.

A dinner was given by the medical officers of the Mediterranean Fleet in honour of Surgeon W. J. Maillard, R.N., M.D. Lond., V.C., at the Malta Union Club on Jan. 13th.

Correspondence.

"Audi alteram partem."

THE DEATH-RATE AND THE WATER-SUPPLY.

To the Editors of THE LANCET.

SIRS,—In the coming Session of Parliament there will be a large crop of Bills for water-supplies. The advocates of moorlands, lakes, chalk springs, and rivers will contend in the committee-rooms over their pet schemes. It may therefore be interesting to your readers to compare the death-rate from fever for the first three-quarters of 1898 with the same period of 1897 in the principal cities of England and Europe. The death-rate has been computed, to avoid decimals, at per 1,000,000 living; those who prefer to consider the question at a rate of per 1000 will find it only necessary to shift the decimal point three spaces to the left (see the table).

One cannot help being struck with the uniformity of the incidence of the fever death-rate for 1897 and 1898 in the same towns. In some towns fever appears to be endemic, whilst in others it is reduced to insignificant numbers. Belfast had during this period a far higher death-rate from fever than any other town in Europe. Belfast, Manchester, Glasgow, Liverpool, and Sheffield obtain their water from moorlands and lakes; nevertheless, the fever-rate is very high.

The year 1898 was remarkable for the small amount of percolation and for many weeks there was absolutely none, consequently it was not surprising to find that in Hull, Portsmouth, Bristol, Brighton, and Croydon—towns which derive their supply from the chalk—the mortality from fever was less than in 1897, but we must expect on the rising of the springs after the late heavy rains that during the next three months there will be a corresponding rise in the fever death-rate. For instance, in the December quarter the death-rate from fever in Croydon went up to 64 per 1,000,000, which is more than two and a half times the other three quarters. Water which has been exposed to air and light for a considerable time and then efficiently filtered is improved in quality, consequently London, Paris, Berlin, Copenhagen, Cologne, Hamburg, Nuremberg, Dresden, Altona, and Vienna have had a very low fever death-rate. On the other hand in the limestone districts of Lenz, Rheims, Metz, Prague, and where the water is obtained from shallow wells, as in the highly cultivated districts about Malines, Bruges, and Namur, the mortality has been excessive owing to pollution of sub-soil water. Antwerp is a good illustration of a town whose supply which is derived from a highly polluted stream (a tributary of the Scheldt) has after treatment by passing through spongy iron and sand filters become a good wholesome water, with a corresponding low fever death-rate.

Great Britain cannot pride herself on being the leader of sanitary progress. Taking 100 per 1,000,000 living as a standard for fever mortality, I find that 13 out of the 22 towns were in excess, whilst on the Continent only 17 out of 51 towns exceeded that figure—a fact not creditable to the Health Department of the Government. In Germany sanitation has progressed by leaps and bounds, with the result of a marked improvement in the death-rate from preventable disease. The Imperial Government has not been hampered by any motives of vote-catching or consideration for the scruples of the conscientious objector.

The reckless manner in which the Local Government Board have in the past sanctioned sewage-farms and cemeteries upon permeable and water-bearing strata from which increasing populations are either at the present time or will in the near future draw their water-supply must inevitably tend to increase the severity of the constantly recurrent outbreaks of preventable disease. Every local authority or water company should be compelled by law to send a monthly chemical and bacteriological analysis of every source, if more than one, of their supply to the Local Government Board who should report the results annually to Parliament and also to the councils within their area of supply. Some sources of supply now in use would be condemned and preventable disease diminished.

I am, Sirs, your obedient servant,
Carshalton, Jan. 15th, 1899. A. H. SMEE, L.C.C.

AN ALCOHOL BATH FOR BURNS.

To the Editors of THE LANCET.

SIRS,—Dr. Theodore Zangger's article in THE LANCET of Jan. 28th describing the use of rectified spirit as a lotion in certain inflammatory conditions where the skin is unbroken is of interest and, I think, of importance. Dr. Zangger's explanation of the benefit resulting is that it is due to a penetration of the skin by the alcohol vapour which is thus supposed to reach and destroy the organisms which are the cause of the localised inflammation. Whether alcohol either as liquid or vapour can destroy the vitality of a septic organism without at the same time also coagulating the protoplasm of the leucocyte or the proteids of the plasma in which it lies is to be very much doubted. One is inclined to attribute the benefit of such a dressing largely, if not entirely, to its frigorific effect. The author, moreover, makes a special point of the necessity for apertures in the protective covering of the dressing.

I have for some time entertained the belief, or rather the hope, that alcohol might have a more useful application in the treatment of burns. The idea suggested itself to me in connexion with a very trivial circumstance. Being in a small hill station in India I burnt the tip of my finger severely. Whisky was the only application at hand and immersing my finger in a vessel of it I was surprised to find a speedy relief from pain. The finger was kept in the spirit for an hour or so and next day the patch of burnt skin separated itself and the cure was complete.

The mortality from burns seems to be very much what it was ten years ago and there seems to have been no material change in methods of treatment, yet the infant who has been burnt or scalded remains a perennial spectacle at all our hospitals. There are certain considerations which make it appear that a more or less continuous bath of alcohol would be an appropriate treatment for a burn. Alcohol is a powerful germicide. We may expect that the suppuration following a severe burn would be kept within aseptic limits and sapræmia avoided. Alcohol coagulates the proteids of serous exudation and should therefore coat a burnt surface with a firm pellicle. It will also coagulate the protoplasm of exposed and injured nerve fibrils with the result that almost all the pain [illegible] at [illegible] surface should be a comparison is wholly misleading because the outbreaks of plague do not develop according to the season or, at any rate, exactly at the same period of each year. The only just comparison is to compare the development of one outbreak with that of another whatever the dates of the year may be, the only difficulty being to fix the corresponding times of their commencements.

The following table gives the mortality in Bombay city of the various castes during the week ending Jan. 10th :—

	Caste.	Population.	Total deaths.	Plague deaths.
Hindus.	Jains	25,225	37	13
	Brahmins...	37,932	27	9
	Lingaits	784	2	1
	Bhatias	7,891	6	—
	Hindus of other castes ...	451,465	640	153
	Hindus (low caste)	45,169	18	20
	Musalmans	155,101	200	12*
	Parsees	47,458	35	5
	Jews	5,021	3	1
	Native Christians...	29,712	30	4
	Eurasians...	4,330	3	—
	Europeans	11,290	4	1
	Negro Africans	146	2	—
	Buddhists...	190	—	—
	Other and unknown castes..	—	4	1
	Totals...	821,764	1,011	220

* This item is probably very fallacious. The Musalmans largely employ quacks and their females seldom see anyone qualified to render a trustworthy return. Moreover, when plague is known a false report is made in order to avoid subsequent interference with their extreme domestic privacy. No death certificates being required the friends give any cause for death they choose. Concealment of plague is therefore especially common in this caste.

As showing the difference in plague administration the health officer for Bombay records that of the 220 cases of plague recorded in the past week only 85 were removed to hospital and only 284 contacts were segregated. During the week 7691 houses were inspected and of these 564 were disinfected and 67 vacated.

Reports have been circulated during the last few days of a recrudescence of plague in Calcutta and it appears that there have been several suspicious cases lately and that two at least have been proved more or less conclusively to be plague. The protection afforded by inoculation at Gaday is remarkable, as the following figures show.

—	Population.	Total attacks.	Total deaths.
Once inoculated ...	3676	8	4
Twice inoculated ...	6706	3	2
Uninoculated	8726	118	74

Objections to all these published records are that the populations are estimated by the last census and from various causes may be very wide of the mark, and that there being no proper identification of inoculated persons reliance can only be placed on verbal statements or the production of a (possibly false) certificate.

The Plague Commission has been sitting at Agra. The only evidence of importance is that of Mr. E. H. Hankin, Chemical Examiner and Bacteriologist to the Government. It is reported that he had experimented for several months with water, clothes, human dejecta, and dust of floors in plague-infected houses without discovering the plague microbe. He had obtained microbes from mud appearing in their microscopic characters to be plague microbes, but they were really not so. He had found the plague bacillus in the nasal secretions of a monkey which when injected into the noses of mice killed them. He is reported to have said that no regular test for the plague microbe had been discovered. He advocated burning the huts of villages or the burning of the earth of the floors.

Jan. 13th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Death under Chloroform.

A REGRETTABLE death under chloroform occurred at the General Hospital on Jan. 27th. A man, aged 41 years, came in for the removal of a sebaceous cyst from his neck below the right ear. Chloroform was given by one of the house-surgeons, the man struggled for a time, and suddenly his heart ceased to beat. A necropsy made by the police surgeon showed evidence of some bronchitis and old pleural adhesions, with alcoholic indications in other parts. An inquest was held subsequently and a verdict in accordance with the medical evidence was returned. I understand that there are rules laid down by the medical committee of the hospital as to the administration of ether as the routine anæsthetic and as to the presence of the senior resident surgical officer on such occasions. The authorities are mindful of the risks in this direction and some time ago appointed two anæsthetists to the hospital. A certain number of cases necessarily occur in their absence when the administration is conducted by one of the resident staff, hence the importance of recognising the precautionary rules and the responsibility in acting upon them.

The Children's Hospital.

The thirty-seventh annual meeting of this institution was held on Jan. 23rd. The report stated that the number of in-patients treated during 1898 was 949, as against 919 the previous year. The out-patients numbered 13,445, against 13,009. The detention-rate was 19·9. The cost of the patients' maintenance was 3*s.* 2*d.* and the officers 7*s.* 5½*d.* per head per week. The total expenditure amounted to £4999 1*s.* 7*d.* The income unfortunately had fallen off, the subscriptions having diminished by £64. Some increase in the size of the out-patient rooms is considered to be necessary and a scheme for enlargement was submitted. It was stated that the lease of the building had 20 years only to run and that provision must be made to meet this contingency. Various donations were promised and votes of thanks passed.

Grocers and Bakers on Self-raising Flour.

A deputation from the Grocers' Association waited upon the Health Committee on Jan. 16th relative to the sale of self-raising flour. For some years this flour has been sold by grocers, but of late prosecutions have been instituted and fines imposed after evidence that there was a certain amount of maize flour mixed with it. The deputation wanted to know if the committee would fix a standard of the quantity of maize flour which might be used—say, to allow 5 per cent. of farinaceous substance other than wheaten flour. The chairman of the Health Committee said that they could not give any undertaking to this effect and that they must carry out the intention of the Food and Drugs Act, but the views of the deputation would have consideration. Following this on Jan. 25th a deputation from the Master Bakers' Association interviewed the Health Committee. They stated that the bakers considered the addition of maize flour to be unnecessary and that in their daily practice they made self-raising flour by simply adding carbonate of soda, tartaric acid, and cream of tartar to wheaten flour sufficient to give it the effervescent property. The chairman of the Health Committee pointed out that all they had to do was to see that the purchaser got what he paid for. It will be interesting to note the future development of these rival claims. There does not so far appear to be very much amiss in the way of adulteration, the maxim to be followed being one of a certain advertised product—if you ask for a particular thing see that you get it.

Death of James Yeomans Totherick, M.D. St. And.

I regret to announce the death of Dr. Totherick which occurred on Jan. 26th at his residence, Park Vale, Wolverhampton. Of Scotch descent, the son of a Methodist minister, Dr. Totherick was educated at the University of St. Andrews where he obtained the M.D. degree in 1862. After this he settled in practice at the village of Sudbury, in Derbyshire, and about 25 years ago went to Wolverhampton. Here he was appointed one of the physicians to the hospital, a post he held until his death. Dr. Totherick was a man of cultured tastes, fond of literary pursuits, finding relaxation from his professional duties among those of similar habits. He took an interest also in public matters, becoming a member of the board of guardians and at one time chairman of that body. Of somewhat reserved manners and critical temperament his qualities were best appreciated by those who knew him best, and to these he was an interesting companion and a good friend. His professional work was performed with careful and attentive consideration. For a year or two past his health has been failing, the symptoms being attributed to a form of pernicious anæmia. Travel and change of scene and surroundings failed to give him permanent relief and towards the end he declined rapidly. He leaves a widow but no family.

Jan. 31st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Royal Infirmary.

THE annual meeting of the trustees of the Royal Infirmary was held on Jan. 30th. The treasurer said that at no period of the history of the infirmary either in the old or in the new building had so much work been done as in the year just closed both as regards in-patients and out-patients. The number of casualties treated had reached the large total of 17,906. The expenditure on the charity had been £13,668 at a cost of £51 9*s.* 4*d.* per bed occupied. The deficit was £2089. Some permanent additions and improvements had been found necessary. More suitable lavatory accommodation for the increasing number of students in connexion with the medical school had been provided at a cost of £350. Financially the year had been disappointing Only one considerable sum from the precarious source of legacies had been recorded, and had it not been for the endowment of a bed by his widow in memory of the late Dr. James Turnbull, a former physician to the infirmary, donations would have been also very meagre. Eight beds were now endowed from donations of £1000 each. The maintenance fund had been drawn upon during the year to the extent of £2749 and the committee deplore the gradual depletion of that fund. The debt on the working expenses now stands at £2089. More patients had been sent to the Woolton Convalescent Institution and other sanatoria. A remarkable fact was elicited at the meeting that in the year 1821, when the permanent and floating population of Liverpool was estimated at 151,000, the subscriptions to the infirmary were £2105, whereas in the year 1898, when the population had increased to 668,545, the subscriptions were only £3200, a difference of only £350 as compared with 70 years ago. Two important changes had taken place during the year in the *personnel* of the honorary medical staff, the first being due to the death of Dr. John Wallace, the gynæcological surgeon, who was succeeded by Dr. T. B. Grimsdale. Mr. Frederick W. Lowndes's period of office as surgeon to the Lock Hospital having expired he was appointed consulting surgeon. To ensure more efficient working of the outdoor department two casualty officers have been appointed who also take charge of the ambulance. Mr. Ralph Brocklebank was re-elected honorary treasurer, an office which he has filled for 20 years. The retiring President, Mr. John Brancker, made the customary donation of 100 guineas.

The New Medical School of University College and the Royal Infirmary.

The land upon which the old medical school buildings are erected has recently been transferred by the trustees of the Royal Infirmary, to whom it belonged, to the governors of University College. The land, consisting of 1800 square yards, together with the old buildings have been handed over to University College at a peppercorn rent for a term of 999 years on the condition that the medical school be rebuilt on plans approved by the committee of the Royal Infirmary and that the new building be always used as a medical school in connexion with the Royal Infirmary and that it be maintained by University College.

University College, Liverpool Biennial Dinner of the Medical Faculty

The medical faculty of University College held their biennial dinner at the Exchange Station Hotel on Jan. 28th under the presidency of Dr. Richard Caton, the chairman of the faculty. The invited guests included the Lord Mayor, the Rev. S. A. Thompson-Yates (the donor of the Thompson-Yates Laboratories in University College), Sir John Brunner, Bart., M.P., Mr. Alfred L. Jones, the Stipendiary Magistrate, the City Coroner, Principal Glazebrook, Mr. Ralph Brocklebank (treasurer of the Royal Infirmary), &c. The toast of the "City of Liverpool" was proposed by Professor Strong and replied to by the Lord Mayor. "The Medical Charities of Liverpool" was proposed by the chairman and responded to by Sir James Poole and Mr. W. P. Hartley. The toast of "University College" was proposed by Mr. Ralph Brocklebank and replied to by Sir John Brunner. The dinner was in every way a great success.

Feb. 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Report by Sir Henry D. Littlejohn on Pulmonary Tuberculosis in Edinburgh.

SIR HENRY LITTLEJOHN, as medical officer of health of the city, has drawn up a report on Pulmonary Consumption in Edinburgh. It begins by saying that the mortality from consumption has been decreasing as a result of improved hygienic surroundings and other causes. He gives a table of mortality from pulmonary consumption in two decades and contrasts it with the total mortality and the mortality from ordinary infectious diseases. From 1878 to 1887 the total death-rate per 1000 was 19 0, for phthisis 2·1, and for zymotic diseases 2·1; from 1888 to 1897 the total death-rate was 18·0, for phthisis 1·8, and for zymotic diseases 1·7. He then proceeds to consider the question: What can be done in a city like Edinburgh still further to lessen the ravages of this scourge? He considers this under a number of heads—1. The corporation must continue the improvement of insanitary areas. 2. He emphasises the necessity of regular cleansing and inspection twice weekly of common stairs in the poorer districts. He evidently dislikes the common stair and prefers the balcony system. 3 He advocates the use of sea-water for cleansing and watering streets and closes. He also advocates the establishment of baths for the poorest classes. 4. He wants handbills and notices posted to lessen the amount of spitting which is so prevalent in public places and public vehicles. 5. He wants various city agencies to distribute bills drawing attention to the danger of the expectoration from phthisical patients and he appends a form of handbill which might be issued. He then enters into a number of interesting statistics dealing with the mortality in the wards of the city, the age, sex, occupation, and class of house occupied by the victims. He further asks the question: Can the corporation interfere with beneficial effect in the course of this disease? and his answer is that he does not see how it can do so. He considers the question of parochial relief and thinks the parish council might get its rules relaxed by the Local Government Board and that it might also arrange to provide a certain amount of beds for the housing and nursing of cases which cannot be attended to at home. He concludes his report by considering the question of notification and he does not see his way to recommend its adoption mainly because of the expense it would entail. He estimates that there are 5000 cases of phthisis in the city He evidently thinks that as regards tuberculosis in cattle the next move cannot be made until Government takes the matter up.

Edinburgh Public Health Committee and Phthisis.

At a meeting of a sub-committee of the Public Health Committee of the Town Council it was agreed to have a conference with the councils of the Royal College of Physicians and the Royal College of Surgeons of Edinburgh, and the principals of the Veterinary Colleges on the treatment of consumption It was also decided that phthisis should be notified and that a circular should be issued containing suggestions and indicating precautions in cases of phthisis.

Gynæcological Appointments to Leith Hospital.

The managers of Leith Hospital have appointed Dr. Brewis and Dr. Haig Ferguson as gynæcologists to the hospital in place of Dr. Berry Hart who has resigned.

Lectures on Teratology and Ante-natal Pathology.

Dr. J. W. Ballantyne is to deliver six lectures on this subject at the University of Edinburgh on consecutive Fridays, beginning on Feb. 3rd. These lectures are delivered on the recommendation of the medical faculty and senators; a suitable recognition of the eminent position Dr. Ballantyne has made for himself in this department.

The Society for the National Registration of Plumbers.

On the evening of Jan. 26th a lecture was delivered in Edinburgh under the auspices of the Society for the National Registration of Plumbers by Dr. W. Leslie Mackenzie, medical officer of health of Leith, on the Hygienics of Diphtheria. The chair was occupied by the convener of the Public Health Committee of the Edinburgh Town Council.

University of St. Andrews.

At a meeting of the University Court held on Jan. 24th the court authorised the expenditure of £250 towards fitting up the new medical buildings and empowered the Business and Finance Committee to provide without delay such other fittings as might be necessary, the total cost not to exceed £1500. It was resolved to proceed at once with the erection of a physical laboratory. The court agreed to advertise for an external examiner in public health. Mr. G. S. Newth, F.C.S., F.I.C., Royal College of Science, South Kensington, was appointed an examiner in chemistry, and Mr. F. G. Proudfoot, M.A. St. And., M.B., C.M. Edin., Oxford, was appointed an examiner in materia medica. It was resolved to intimate to the Senatus Academicus that the court propose to appoint Mr. A. T. Masterman, B.A., D.Sc., to be lecturer on embryology. The court also sanctioned the appointment as from the commencement of next summer session of Mr. James Gray, M.A. St. And., M.B., C.M., F.R.C.S. Edin., as assistant to the professor of surgery in the University College.

Curious Action against a Medical Man.

The action brought against Mr. James Devon, medical officer of the Duke-street Prison, Glasgow, for alleged assault on an engineer who was at the time undergoing a sentence of imprisonment, has been dismissed with expenses against the pursuer. It will be remembered that the act complained of was the vaccination of the prisoner, and the medical officer was charged with misrepresentation and with the use of impure lymph and of an unclean instrument. The sheriff has found these charges to be unsubstantiated and has decided that as the pursuer offered no objection to the performance of the operation therefore no legal assault was committed.

Glasgow Eye Infirmary.

At the annual meeting of the subscribers held on Jan. 25th, Sir Jas. King, Bart., being in the chair, it was intimated that the increase in the number of both in- and out-patients had forced the directors to consider the question of enlarging the infirmary. At present it has not been decided whether the addition should be made to the older buildings in the East-end or to the larger and more recent hospital in Berkley-street. The report announced with regret the retirement of Mr. Munsie who has for many years acted as treasurer to the infirmary.

Glasgow University.

Negotiations have been in progress with a view to avoid a contest for the seat on the court rendered vacant by the death of the Rev. T. W. King. So far no agreement has been reached and it seems probable that a contested election will be inevitable. Mr. King belonged to the so-called "university reform" party which by an amicable arrangement has for some time divided the representation with their more conservative opponents. No active steps have yet been taken in connexion with the vacant chair of Pathology but it is understood that there will be several local candidates. The salary attached to the chair is £1100, private practice being forbidden. The patronage is in the gift of a special board of curators four of whom are nominated by the University Court and three by the directors of the Western Infirmary. This arrangement ensures the election of the same individual both to the University chair and to the position of pathologist to the infirmary.

Feb. 1st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dublin Metropolitan Technical School for Nurses.

THE annual meeting of the governing body of the above school was held on Jan. 20th, the chair being filled by Mr. R. L. Swan, President of the Royal College of Surgeons in Ireland. The honorary secretary read the report, from which it appeared that during the past year 124 candidates, from the five Dublin hospitals which coöperate with this institution, had attended the lectures of Dr. E. MacDowel Cosgrave on anatomy, physiology, and hygiene. The education of nurses is assuming additional importance in Ireland owing to the fact that many appointments are likely to be made under the new Local Government Board regulations.

Death of Sir John Nugent.

Sir John Nugent, who was widely known in Ireland for many years, died in London on Jan. 26th, having reached the venerable age of 95 years. Sir John Nugent was long ago medical attendant to Daniel O'Connell who had a very high opinion of his ability. He subsequently became a Commissioner of Lunacy in Ireland and his reports as Inspector of Asylums were recognised as especially valuable. The late Sir John Lentaigne was associated with him in this work for many years.

Irish University Education.

The question most discussed in Ulster at present is Mr. Balfour's proposed settlement of the difficult question of Irish university education. Briefly put, the Leader of the House of Commons proposes to establish two new teaching universities—one in Dublin and one in Belfast—on precisely similar lines. The one in Belfast is to absorb the existing Queen's College; the one in Dublin would probably have its headquarters in the present Royal University which would then cease to exist. Both universities are to be subject to the Test Acts; all scholarships and fellowships paid out of public funds are to be open to competition irrespectively of creed. No public endowment is to be given to chairs in Philosophy, Theology, or Modern History; professors are to have a right of appeal against unjust dismissal and the number of clergy on the governing board is to be strictly limited. In Ulster there are many who oppose Mr. Balfour's scheme as they conscientiously object to making education denominational, forgetting that even at the present time the Royal University is indirectly denominational; but, on the other hand, there is an increasing body of thoughtful men in Ulster who feel that Mr. Balfour has made out a most convincing case for his proposals and who argue that the time has come to make an attempt to settle this vexed Irish question. Those who are personally engaged in college and university work in Ulster are largely in favour of Mr. Balfour's scheme. They believe that the time has arrived for a teaching university, "properly equipped," to be established in such a great centre as Belfast. They fail to see why Ulster students should, after receiving all their education in that city, be compelled to go to Dublin to be examined for degrees in the various faculties of the Royal University. There might in former years have been some ground for this arrangement, but it must be conceded that all this has changed. Belfast has grown to be a city larger in population than Dublin and educational matters have made enormous strides in that city where there is now quite a number of educational institutions. In Queen's College there is an Arts Faculty, a school of engineering, and a Faculty of Law, all doing admirable work. There is also a very large medical school whose students form more than one-half of all those who graduate in medicine in the Royal University. The Queen's College in Belfast has been keeping well abreast of recent scientific advancements, as is evidenced in the very modern chemical, physiological, and pathological laboratories which were formally opened two years ago by Lord Lister on the occasion of the jubilee of the College. There are excellent special hospitals of all kinds in Belfast and at the present moment the architect who designed the Birmingham Hospital is preparing plans of the new Royal Victoria Hospital towards the building of which—in commemoration of Her Majesty's jubilee—a sum of more than £100,000 has been contributed by the citizens who felt that the present old Royal Hospital was not equal to the increasing demands made upon it. There are thus ample opportunities for clinical teaching so essential to a medical school. I mention all these points to show that not only has the time come, but that matters are quite ripe for the establishment of a university in Belfast. It is surely time that Ulstermen had a university "fully equipped" in every faculty, suited, as Mr. Chamberlain believes such an institution should be, to the environment in which it is located—a university "that will train schools of competent men in all branches of knowledge that have any national importance." One thing, I think, all true lovers of education are agreed upon is that the present state of affairs is well-nigh intolerable. University education in Ireland may and, I believe, can be made better. At any rate, in the opinion of many it cannot be worse than at present in its practical working. Not only are all parties dissatisfied with the present arrangements, but the uncertainty as to what may be the ultimate outcome is doing incalculable mischief. Many graduates of the old Queen's University refuse to allow their sons to go to the Royal University as they fear it in turn may soon be defunct, and so at the present moment many of the Ulster youths are being sent out of the country for their university education. Mr. Balfour deserves the greatest praise for his courageous attempt to settle a question which has baffled so many statesmen. Those who object to his proposal to establish two more universities should recollect that at present there are but two in Ireland and that of these only one is a teaching body; while there are four in Scotland, and in England in addition to Oxford, Cambridge, London, Durham, Victoria, and Wales, Birmingham is likely soon to have a university. There are 15 in France and 21 in Germany. Whatever may be the ultimate issue of Mr. Balfour's proposals everyone in Ireland (where opinion is so divided) believes that he is influenced by the highest motives and the utmost sincerity in his desire to settle the question of Irish university education.

Medical Men and the New Urban Councils.

Last week I stated that the new rule issued by the Local Government Board, to the effect that no paid officer engaged in the administration of the Poor Relief (Ireland) Acts, 1838 to 1898, would be eligible to serve as a county councillor under the Local Government (Ireland) Act, 1898, would, if applied to county borough councillors, disqualify two members of the Belfast City Corporation—Alderman Bigger, M.D. R U.I, and Dr. John Barron. The town clerk has just received an intimation from the Local Government Board to the effect that their order does not appply to the councils of municipal boroughs and consequently I am glad to announce that the two medical gentlemen are not affected by it.

The Samaritan Hospital, Belfast.

At the annual meeting of the Samaritan Hospital held on Jan. 30th it was reported that during the past year 712 patients had been treated in the extern department while 194 had been admitted to the wards. 147 operations were performed (including 25 abdominal operations) with three deaths. A new operating theatre has been added. There is a balance of £200 on the wrong side, the subscriptions and donations for the year showing a decrease, while the household expenditure has increased. The new wing has enabled the surgeons to give relief to a greater number of sufferers. It has been decided to form a ladies' committee.

Jan. 31st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Method of Purifying Air.

AT the meeting of the Academy of Medicine held on Jan. 24th M. Laborde, the head of the physiological department at the Faculty of Medicine, presented a report upon some work done together with M. Jaubert embodying a discovery which apparently possesses great practical interest. The report dealt with a chemical preparation which by one and the same operation removes the carbon dioxide from respired air as well as the watery vapour and other expired products and also restores the exact quantity of oxygen which has been used up. In a word, this substance by simple contact with respired air regenerates it completely and gives back all its primary properties. According to M. Laborde and M. Jaubert three or four kilogrammes of this substance allow a man to live 24 hours in a confined space without any renewal of the air from outside. Experiments made upon guinea-pigs shut up under bell glasses have been very satisfactory. Other experiments have been made upon human beings by means of a mask so constructed that it allows the passage of air, regenerated by means of M. Laborde's apparatus, to the respiratory tract. This discovery would appear to have a great practical use for persons obliged to work in irrespirable media, such as miners, firemen, sewermen, and divers. M. Laborde considers that his invention will also be applicable to submarine boats.

The Hygiene of Bakers' Ovens.

The Council of Hygiene has just come to a decision rendered necessary by certain cases of poisoning following upon the consumption of bread baked by certain bakers. A police regulation of 1877 had forbidden bakers and pastry-cooks to heat their ovens with wood which had been painted or treated in any way with chemicals. As a matter of fact, some 60 persons who lived in the same quarter and were supplied by the same baker were one morning very nearly poisoned. Examination of the oven and the dust from it revealed the presence of a large quantity of salt of lead. Little by little, however, the strict surveillance as to this point was relaxed, all the more easily because bakers began to use new ovens which were heated by a fire outside them, and as all danger appeared to be avoided by this fact both bakers and pastry-cooks heated their furnaces with any and every kind of wood. Naturally they took to the cheapest kinds and so used wood from old houses whether painted or not, old sleepers from the railway impregnated with creasote and sulphate of copper, and even disused blocks of wood paving. The new regulation of the Council of Hygiene demands the strict application of the old regulations, basing the claim on the fact that such wood as is now used may contain salts of lead, copper, or arsenic which are volatilised by the heat and deposited upon the floor or roof of the oven.

The Transmission of the Agglutinative Property in Typhoid Fever by Way of the Placenta.

At the meeting of the Hospitals Medical Society held on Jan. 13th MM. Mosso and Frenkel communicated a report on the above subject in which they drew the following conclusions: (1) the typhoidal agglutinative property can pass from the mother to the fœtus unaltered by way of the placenta; (2) this property is found in a full-time child when born of a mother who has suffered from typhoid fever during gestation; (3) more feeble from the beginning in the child than in the mother, it becomes progressively weaker after birth and appears to be a kind of passive loan arising from the filtration of agglutinative matters through the cellular barriers of the placenta; (4) the energy of the agglutinative powers in the mother and especially the length of time during which the agglutinative matters impregnate the placenta are important conditions of the transmission of the agglutinative powers from the mother to the child; and (5) the agglutinative powers of the mammary secretion as a rule are far weaker than those of the blood but in some cases attain a considerable magnitude—e g., as much as 1 in 100 The same two conditions—namely, energy and duration—which obtain as to the transmission of agglutinative powers by way of the placenta without doubt exist with regard to the transmission from nurse to suckling.

Conviction of a Medical Man for Illegal Practice.

On Jan. 2nd the Tribunal of Dieppe convicted a young medical man who, having finished his studies and being on the eve of sending in his graduation thesis, had seen some patients on behalf of one of his colleagues. He had also done some work for the Assistance Publique. He had only done what plenty of other young medical men do who see an advantageous opening and jump at it while losing no time in complying with the formalities of the last examination which are very tedious He had arranged for the publication and defence of his thesis The law allows for cases of this sort provided that the would-be practitioner applies to the Prefect for a permission which is granted provisionally for a term of three months. The tribunal, however, condemned this practitioner because he had not asked for this permission which, by the way, hardly anyone ever does ask for. The medical associations have been much moved by this underhanded severity, for the conviction stands as being for illegal practice. The severity shown in this case is all the more astounding when compared with the tolerance shown by the tribunals to bone-setters and quacks of all kinds who have carried on their "practice" for years in spite of the complaints made by medical associations. The most piquant feature in the case is that the practitioner being advised of his prosecution hastened to fulfil all the necessary formalities so that when he appeared in court to be condemned for illegal practice [illegible] ery [illegible] ector of medicine.

Jan. 31st.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Baths of Weissenburg.

THE large hotel of the baths of Weissenburg in the Simmen Valley near Thun (Bernese Oberland) which was burnt down last spring has been rebuilt and will be opened in May, 1899. The springs of Weissenburg which contain considerable amounts of carbonate and sulphate of magnesia and calcium are well known for their efficacy in phthisis.

Medical Students at Swiss Universities.

The number of medical students studying at the five Swiss universities steadily increases from year to year; it runs up to 1181 for the winter term, 346 of whom are ladies (mostly Russian, German, Austrian, and American). The medical faculty of Bâle numbers 126, Lausanne 158, Berne 240, Geneva 297, and Zürich 360.

Prevention of Infective Diseases.

Some years ago the sanitary authorities of Zürich in order to prevent the spreading of infective diseases urged the medical practitioners to supply themselves with linen coats easy to disinfect to be left outside the sick room of private patients. The authorities offered to disinfect these coats as soon as notice was given of the recovery of the patient or of the removal of the same to an infection ward, and also offered to restore the coat properly disinfected to the owner. As only a few of the Zürich practitioners availed themselves of this opportunity the sanitary authorities have taken one step more and an important one. Imitating the example of Lausanne they now offer on notification of any case of diphtheria or scarlet fever immediately to send a disinfected linen coat to the patient's house to be put on during the time of treatment free of charge. It is to be hoped that many medical men will now avail themselves of this opportunity of preventing the spread of infective disease. Typhoid fever and whooping-cough being not so easily transmitted by means of third persons if a due amount of necessary precaution is taken and measles and German measles being often very prevalent and not so dangerous these precautions have had to be limited to scarlet fever and diphtheria. This seems especially necessary in the latter case as a great many more cases are now treated at home since the antitoxin treatment in the earliest stage insures the same results as hospital treatment.

Zürich, Jan. 30th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Florentine School: its New Clinical Buildings.

THE event of the week has been the opening on Jan. 23rd of the new clinical wards in the Hospital of Santa Maria Nuova—wards dependent on the Istituto di Studi Superiori, or school of pre-graduate and post-graduate instruction. In addition to these purely clinical accessions to its resources the Istituto has an Istituto Antirabico, inaugurated likewise on Jan. 23rd, and at last putting Florence on an equal footing with Milan, with Rome, and with Naples in dealing with hydrophobia prophylactically and clinically. Never to despair of Italy is the moral to be deduced from the event solemnised so impressively and so eloquently on Jan. 23rd last. In spite of Tuscany's brilliant record in the annals of the healing art her capital has been but ill provided with the means of clinical and laboratory instruction—the *personnel*, as is usually the case throughout Italy, being far superior to the *matériel.* Some eight years ago it was thought a mighty advance when Professor Federici, who held the chair of clinical medicine, had at his disposal two clinical wards, three rooms for laboratory work, and an amphitheatre for lectures. His not less able and accomplished successor Professor Grocco was barely installed in the clinical chair when he set himself to improve on this state of things. He found the whole teaching apparatus representing a money value of less than £80, and to-day, after six years of indefatigable appeals, canvassings, and personal contributions, he has raised the teaching resources of his chair to four clinical wards, comprising 70 beds, with four rooms for paying patients, accommodation for assistants, and laboratories for every department of pathological research (chemical, microscopical, and bacteriological) second to none in Italy and worthy to rank with those of the higher French or even German schools. Add to this the publication of a weekly clinical record embodying the best Florentine work, a reading-room where more than 60 journals in four languages may be consulted, and a library of 1100 volumes, and some notion will be formed of the accessions made to the resources of clinical teaching in Florence within six years. Nor is this all. An Istituto for the practice of the Pasteur methods in rabies has been opened contemporaneously with the new clinical wards and Professor Grocco is already laying the lines of a department for medical gymnastics (*iatro-meccanica* and Swedish massage), to be a *fait accompli* in two years, and a department for the preparation of "sieri curativi" (seratherapy in all its ramifications), to be completed in a few months. Thanks to the head of her clinical and consulting practice Florence will begin the twentieth century with a teaching equipment she has never yet known, and if her achievement has hitherto been so honourable in spite of every conceivable disadvantage, what may it not become when her students are put level with their contemporaries in the matter of facilities and resources hitherto denied them? It was this prospect that inspired Professor Grocco to one of the most glowing passages in his finely classical address to the great audience of Jan. 23rd last. Instead of the one "adjutant" and two assistants of his predecessor he has now, besides the "adjutant," 16 assistants, representing posts so eagerly coveted throughout Italy that this year he has had to refuse the application of more than 30 candidates from nearly every school. Phalanx after phalanx of well-trained workers are in this way sent forth annually to fill chairs, to act as *privat-docents*, and to serve in the various departments of hygiene, public, naval, and military. Florence, moreover, while not a university, but simply a training school, is also a resort [illegible]graduate study as is implied in the very title, "I[illegible] Studi Superiori," or, as Professor Grocco eloquent[illegible] they, her task is not only "di istruire i giovani per la [illegible], a di perfezionarli una volta laureati" (to prepare youths for graduation but to carry them towards perfection when they have graduated). "From my heart," he added, "I yearn for the day when, given a sufficient development and a sufficient endowment for every laboratory, there may be added to the class list of subjects for undergraduates a special class list for medical men 'perfezionandi' (to be perfected), so that the practitioners who wish to enlarge their theoretical and practical knowledge may really find in this faculty a well-devised and coördinated series of courses in lecture room and laboratory which may assist them in the attainment of their object. To no city is our 'pious wish' more appropriate than to Florence, the seat of delightful repose, the intellectual centre *par excellence.*" The entire discourse was worthy of the occasion and of its author.

Jan. 28th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Care of the Insane.

A LITTLE more than two years have elapsed since the institutions for the insane of New York city were transferred to the State and over three years have passed since the institutions in King's County became a part of the State hospital system. All of the insane, except those in private institutions, are now in well-organised and well-managed State hospitals and have the advantages of curative treatment. While the hospitals have been greatly improved during the past year in every respect the cost of administration has been greatly reduced, the per capita cost during that period being only $184.16—the lowest in the history of the State hospital system. Prior to 1893 the cost of caring for patients in the State hospitals averaged more than $222 per year, a reduction amounting to more than $38 per patient. How great this economy is can be readily appreciated when it is stated that there are nearly 21,000 insane in the State hospitals of New York at the present time. In other words, the expenditures during the past year were about $600,000 less than they would have been had the rate of 1893 prevailed. In every department of the State hospitals improvements have been made. The patients are better clothed, the buildings are better furnished, the sanitary arrangements are improved, and the food-supplies are better in all respects. Special care is now being given to the eyes and teeth of the patients. Large numbers of these unfortunate people have been greatly neglected in these respects in the past. With the improvement in the care of the insane during the past few years there was at first a considerable increase in the number of admissions, many people formerly preferring to keep their friends at home rather than risk their having to suffer in public institutions. It is believed, however, that the increase by reason of such causes has reached a maximum, as the figures tend to show that the tide is strongly setting the other way. For example, the net increase for the year 1895–96 was 653; for 1896–97, 813; while for the year just passed the net increase has dropped down to the unprecedentedly low figure of 634. Likewise in the matter of new admissions from homes for many years prior to 1895–96 there had been a marked increase every year over the preceding year. In 1895–96 the new admissions were 4688, while in 1896–97 they dropped down to 4370, and during the past year the number has remained substantially the same, while from the experience of former years an increase might have been expected, both on account of the increase of population and for other reasons which were formerly in operation. This all tends to show that insanity is not on the increase, as is popularly supposed. This has been somewhat hastily assumed to be the case because the increase of the insane has been greater than the increase in the population, people not reflecting that as institutions improved friends were more and more willing to trust their relatives to the care of the State hospitals. The rate of recovery has also increased. In 1895–96 it was 948, in 1896–97 it was 951, while during the past year it gained nearly 10 per cent., 1018. This is really the crucial test of the whole system and shows the advantage of transferring the institutions of the County of New York and King's County to the care of the State. It is quite likely that this rise will continue It obviously must with better food, better clothing, better medical attendance, and better opportunities for amusement and recreation. Excellent training schools for nurses in State hospitals have been established throughout. All candidates are now obliged to pass a uniform examination on the same day. A graduate of a training school receives a considerable increase in wages and this conduces to the improvement of the service in every way. By this means experienced employés are obtained and the patients reap the benefit.

The Alien Poor sent to their Homes.

The State of New York has an officer devoted to searching out dependent persons who have come to this State from abroad. The following facts are gathered from his annual report. During the fiscal year ending Sept. 30th, 1898, there were removed 214 alien poor to their homes in different countries in Europe. They were found in almshouses, asylums and hospitals, and other charitable institutions in this State, and their condition at the time of landing in this country as brought out by the inquiries was as follows: crippled, 15; epileptic, nine; paralytic, five; aged and infirm, 26; feeble-minded, 54; vagrant and diseased, 43; and otherwise disabled, 62 These had been furnished transportation to this country as follows: by cities, towns, and other municipalities, 18; by benevolent associations, societies, and emigration agencies, 59; by padrones, contractors, corporations, and individuals under agreement to labour, 23, and by relatives, guardians, and friends, 114. By their own statements they were found to have landed as follows: at the port of New York, 192; at other United States ports, 15; and at various Canadian ports, seven. After careful examination these persons were returned to their homes as follows: to England, 33; to Ireland, 21; to Germany, 44, to Austro-Hungary, 55; to Italy, 43; to Russia, nine; to Sweden, three; and to Holland, Switzerland, Scotland, Bulgaria, Denmark, and Norway, each one. The total expenditure of these removals was $5328 26; the average per capita cost, $24 90. Since this Act came into force in 1890 up to Sept. 30th, 1898, there have been 3350 removals made at a total expenditure of $75,322 25, or an average per capita of $22 48.

Alleged Hypnotic Power over a Jury.

Not one of the least sensational features of a recent prosecution in New York City for blackmailing was the alleged hypnotic power of the defendant's wife. According to the newspapers no juror could look her in the eyes and render a fair and impartial verdict. Whether it was that the court really did fear that she would hypnotise the jury or that she was caught ogling the jury and making signs to them the judge as far as possible kept her out of the court-room or required her to take a retired seat so that the baleful influence of her eyes would not be felt. The jurors were unable to agree, but after the trial each juror declared that the woman's eyes did not have the least influence upon him.

Cleansing the City of Havana.

The colossal task of putting every dwelling in the city of Havana into good sanitary condition is progressing Surgeon-Major Davis has hired 100 resident physicians for house-to-house inspection to compel obedience to the new regulations. All cesspools under houses are to be closed and sealed. Garbage is to be removed daily. It is expected that the city will be in a fair sanitary condition within three months, without underground sewerage. The old residents regard these new health regulations as unnecessary and meddlesome and even some well-to-do and well-informed persons, when making their objections, describe themselves as "healthy enough." To-day 1000 people are engaged in the work of cleansing the streets and public buildings.

Jan. 13th.

Obituary.

EDMUND JOSEPH FURNER, F.R.C.S. ENG., L.S.A.

THE medical profession has lost one of its most venerable members by the death of Mr. E. J. Furner who passed away on Jan. 1st at his residence in Brunswick-square, Brighton. A member of a well-known Sussex family, he was born in Brighton on Dec. 13th, 1805, and there he spent the greater part of his long life. One of his brothers was judge of the Sussex County Court and another brother, Mr. Robert Furner, gave the town a valuable collection of prints which has been named after him. Having chosen the medical profession Mr. Furner studied at St. George's Hospital and the Windmill-street School and qualified himself to practise by becoming L.S.A. in 1828 and M.R.C.S. Eng. in 1829. After a voyage to India as a ship's surgeon he was appointed house surgeon to the Sussex County Hospital, eventually rising to be surgeon, a post which he held for 32 years, and on his resignation of it in 1876 he was presented with an illuminated address by the physicians and surgeons. From that time to the day of his death he was consulting surgeon, so that his connexion with the hospital continued from first to last for nearly 60 years. Mr. Furner was admitted F.R.C.S. Eng. in 1854. In 1836 he published a case of ligature of the external iliac artery for femoral aneurysm and in 1863 a successful case of ligature of both subclavian arteries for axillary aneurysm. Up to the time of the brief illness which ended in his death the deceased retained some degree of activity and his faculties were but little impaired. He was a widower and has left two sons, one of whom is a surgeon to the Sussex County Hospital.

EDWARD NICOLLS CARLESS, M.D., C.M. ABERD., L.F.P.S. GLASG., J.P.

DR. EDWARD NICOLLS CARLESS died at his residence, Lansdowne House, Devizes, last week. The deceased received his medical education at the University of Aberdeen where he graduated M.B. and C.M. in 1871; the same year he also took the qualification of L.F.P.S. Glasg. In 1897 he was admitted M.D. Aberd. Dr. Carless was extremely popular and highly respected in Devizes where he was medical officer of health, consulting surgeon to the Cottage Hospital, surgeon to the prison, and also medical officer of the 1st District of the Devizes Union. The deceased took a great interest in the Volunteer movement and was until recently Surgeon-Lieutenant-Colonel in the 2nd Volunteer Battalion Wilts Regiment. Dr. Carless was a Justice of Peace for Devizes and the middle division of Wiltshire. He will be greatly missed in Devizes and much sympathy is felt for his widow and children. The funeral which took place on Jan. 28th was largely attended; amongst those present were Mr. C. E. Colston, M.P., Captain Sterne, R.N. (chief constable of Wiltshire), the medical practitioners of Devizes, the mayor and corporation, the Devizes detachment of Volunteers, and other representative bodies.

GEORGE FREDERICK FARR, M.R.C.S. ENG., L.R.C.P. EDIN.

MR. G. F. FARR, of Kennington-road, S.E., who died on Jan. 11th at his residence, Penrhyn Lodge, Twickenham, had been for nearly 40 years in practice in the neighbourhood of Kennington. His medical education was received at Guy's Hospital and in 1859 he took the diploma of the Royal College of Surgeons of England, supplementing it in 1860 by the Licence of the Royal College of Physicians of Edinburgh Mr. Farr was a man widely known and highly esteemed by a large circle of acquaintances and patients. He was a Fellow of the Obstetrical Society of London, a member of the British Medical Association, surgeon to the L Division of the Metropolitan Police, and also surgeon to Scotland Yard. Mr. Farr's death, which occurred somewhat suddenly, was due to cerebral hæmorrhage. He has left a widow, four sons, and three daughters.

JOHN HAYBALL PAUL, M.D. ST. AND., F.R.C.P. EDIN., F.R.C.S. ENG.

THE death is announced of Dr. John Hayball Paul which occurred at his residence, The Terrace, Camberwell, on Jan. 29th. Dr. Paul became a Member of the Royal College of Surgeons of England in 1840 and a Fellow in 1859. In 1854 he graduated as M.D. at the University of St. Andrews, became a Member of the Royal College of Physicians of London in 1859, and a Fellow of the Royal College of Physicians of Edinburgh in 1858. He was for many years treasurer and at the time of his death emeritus treasurer of the Medico-Psychological Association of Great Britain and Ireland. He was appointed treasurer in 1864 and in 1895, as reported in THE LANCET of Oct. 5th of that year, was presented with an illustrated memorial and a silver bowl by Dr. Nicolson, the President, on behalf of the members.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. A. Klein has been recognised as *privat-docent* of Hygiene.—*Berlin:* Dr. Friedrich August König has been recognised as *privat-docent* of Surgery.—*Buffalo:* Dr. E. H. Long has been appointed Professor of Therapeutics and Materia Medica.—*Giessen:* Dr. Georg Sticker, who went to India in 1897 to study leprosy and the plague epidemic, has been appointed Extraordinary Professor of Medicine. He himself suffered from bubonic plague contracted during the post-mortem examination of a plague patient. Dr. Heinrich Walther has been appointed Extraordinary Professor of Gynæcology.—*Göttingen:* Dr. Schreiber has been recognised as *privat-docent* of Internal Medicine.—*Greifswald:* Dr. August Martin of Berlin has been appointed to the chair of Gynæcology and Midwifery in succession to Dr. Pernice, who is retiring because of failure of health. The new professor is a son of the well-known gynæcologist, Professor Eduard Martin of Jena.—*Heidelberg:* Dr. Otto Cohnheim has been recognised as *privat-docent* of Physiology.—*Kieff:* Dr. Bushueff has been recognised as *privat-docent* of Internal Medicine.—*Kiel:* Dr. Helferich of Greifswald has been elected to succeed Dr. von Esmarch in the chair of Surgery.—*Lausanne:* Dr. Rabow has been appointed to the chair of Materia Medica and Therapeutics in succession to Dr. Bourget; Dr. A. Combe, *privat-docent* of Pædiatry, has been appointed Extraordinary Professor.—*Leipsic:* Dr. Paessler has been recognised as *privat-docent* of Internal Medicine.—*Marburg:* Dr. Eberhard Nebelthau has been appointed Extraordinary Professor of Physiological Chemistry and Physics.—*New York (Polyclinic):* Dr. Charles H. Chetwood has been appointed Professor of the Surgery of the Genito-urinary Organs.—*Prague (German University):* Dr. Hugo Wiener has been recognised as *privat-docent* of General and Experimental Pathology.—*St. Petersburg (Military Medico-Chirurgical Academy):* Dr. N. Andogski has been recognised as *privat-docent* of Ophthalmology and Dr. V. Levashoff as *privat-docent* of Hygiene.—*San Francisco (Cooper Medical College):* Dr. Wm. Fitch Cheney has been appointed Professor of Medicine and Dr. Emmet Rixford and Dr. Stanley Stillman have become Professors of Surgery.

UNIVERSITY OF CAMBRIDGE.—At a meeting of the trustees of the John Lucas Walker Studentship in Pathology held on Jan. 27th, W. Myers, M.A., M.B., B.C. Cantab., B.Sc. Lond., was elected senior student and E. Sydney St. B. Sladen, M.A., M.D. Cantab., was elected junior student. Dr. Myers is working under Professor Ziegler at Freiburg and Dr. Sladen is working at the Cambridge Laboratory.—The Downing Professor of Medicine (Dr. Bradbury) has appointed as his assistant Mr. I. L. Tuckett, Fellow of Trinity College, in the place of Dr. Marshall, recently elected Professor of Materia Medica at St. Andrews.

JENNER SOCIETY.—At the meeting of the Cirencester Board of Guardians and Rural District Council held on Jan. 16th, it was decided, on the suggestion of the medical officer of health (Dr. F. T. Bond), to request the Local Government Board to sanction the small expense which would be incurred by procuring from the Jenner Society vaccination literature for distribution amongst boards of guardians and their officers.

A BISHOP ON VACCINATION.—The Bishop of Bath and Wells, preaching at Weston-super-Mare on Jan. 15th, remarked that we ought not to be neglectful of our physical welfare and that if we were so foolish as to relinquish vaccination and thereby *run the risk of small-pox*, could we expect the Divine Power to be put forth to deliver us from that from which our own knowledge should have saved us?

CARDIFF SCHOOL BOARD.—At the meeting of the Cardiff School Board held on Jan. 20th Dr. W. T. Edwards was unanimously elected vice-chairman.

PROPOSED CARDIFF SEAMEN'S HOSPITAL.—In 1897 Lord Bute promised a subscription of £5000 towards the proposed Seamen's Hospital for Cardiff conditionally upon the fund reaching £25,000. Unfortunately up to the present the amount only reaches £7000 and Lord Bute now offers to increase his subscription to £10,000 providing that another £7000 is raised. It is thought that this amount will be raised as such an institution is much needed in a large seaport like Cardiff.

PRESENTATIONS.—The retirement of Mr. Alfred Cooper from the staff of St. Mark's Hospital with which he had been connected for 34 years was not permitted to take place without some recognition by his many friends belonging to the institution. Accordingly on Jan. 25th he was presented, at the house of Mr. Swinford Edwards in Harley-street, with a Chippendale clock and silver cigarette box, subscribed for by some members of the committee of the hospital, his colleagues, and old house surgeons. Upon the clock was a suitable inscription in commemoration of the occasion. Mr. Edwards in making the presentation alluded to the immense amount of human suffering which Mr. Cooper must have relieved during his long term of office and pointed out how much of the financial prosperity of the hospital had been due to Mr. Cooper's influence.—On Saturday last, Mr. J. St. John Murphy, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Grange Town, Yorks, on the occasion of his leaving the town after a residence there of twelve months, was entertained at a dinner by his friends and presented with an illuminated address and a gold-mounted walking stick.—At the Assembly Rooms, Cheltenham, on Jan. 23rd, the Mayor (Alderman G. Norman) presented the late mayor, Mr. Richard Rogers, L.D.S. R.C.S.I., with his portrait in oils, a massive silver gilt bowl, together with an illuminated address in an album, and a diamond horse-shoe brooch for

Mrs Rogers This testimonial, which cost £275, was defrayed by public subscriptions and was presented to Mr Rogers as a mark of the esteem and respect felt for him and for the excellent manner in which he had performed the duties of mayor for the past three years —At the Clifton Grand Spa, on Jan 26th, a complimentary dinner was given to the local executive officers during the visit of the British Association to Bristol last year—Mr J W Arrowsmith, the honorary treasurer, and Mr Arthur Lee and Dr Bertram Rogers the joint honorary secretaries A presentation of a silver salver was afterwards made to each of these gentlemen.

THE LATE DR HENRY MARSHALL — On Jan 18th, in the presence of a large congregation, Bishop Bromby dedicated a side altar which has been erected by subscription in the Lady Chapel of St Raphael s Church, Bristol, as a memorial to the late Dr Henry Marshall of Clifton The Bishop, in his address, paid an eloquent tribute to the memory of Dr Marshall whose life and work he held up as a brilliant example

DINNER TO SURGEON W. J. MAILLARD, R N, M D, V C—The medical officers of the Mediterranean Fleet entertained Surgeon Maillard to dinner at the Malta Union Club on Jan 13th, 1899, in honour of his being awarded the Victoria Cross for his brave actions on the recent disturbance at Crete Commander Vaughan Lewes, D S O, and the other officers of H M S *Hazard*, were invited to meet him About 30 sat down to dinner under the able presidency of Deputy Inspector General Martin, the proceedings being enlivened by the band of H M S *Revenge*, kindly lent by Rear-Admiral Sir Gerard Noel, K C M G After the Queen's health had been drunk, the president, in a most eulogistic speech, proposed the health of the "Guest of the evening" and congratulated him upon receiving from Her Majesty the most coveted of honours, the Victoria Cross Surgeon Maillard, in response, thanked his brother officers for the honour which they had done him and said that he was more than pleased to have done something for the honour of the medical branch of the navy and felt very much their sympathy and appreciation

LITERARY INTELLIGENCE — The first number of a new monthly review named *Le Mois Médical* appeared in January, it is published by Messrs J B Baillière et Fils, 19, rue Hautefeuille, Paris The subscription is one franc for all countries Messrs Baillière have also sent us their general catalogue of scientific works (114 pages 8vo), containing the title, date, price, number of pages, and many indications of the nature of the contents of about 5000 books and pamphlets on medicine, natural science, agriculture, veterinary medicine, physics, chemistry, &c It is forwarded to any address for 50 centimes, the cost of postage

MEDICAL MAGISTRATES —The following gentlemen have been appointed magistrates for the colony of New South Wales —G T C Adams M D Camb, L R C P, L R C S Edin, L F P S Glasg, of Melbourne, W Atterbury, M D Irel, M R C S Eng, of Catherine Hill Bay, N S W, F W Kane L R C P, L R C S Edin, L F P S Glasg, of Bourke N S W; W M Lyttleton, M D Columb, L R C P Edin, M R C S, of Adelong, N S W, C S Bowker, L R C P Lond, M R C S, of Tumut, N S W, S C Watkins, M R C S Eng of Manly (Sydney) N S W, and T N Wright L R C P Lond, M R C S Eng, of Stroud N S W—Mr E M Pain, M B, Ch M Syd, of the Prince Alfred Hospital, Sydney, has been appointed a magistrate for the colony of New South Wales

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub Editor, not later than 9 o clock on the Thursday morning of each week, for publication in the next number.*

ANDREW J F L.R.C P Edin, M R C S, has been appointed Officer of Health to the city of Hawthorne, Victoria Australia, vice T O F Alsop

BAILEY, JOHN GEORGE M B, C M Edin, has been appointed Senior House Surgeon to the Bury Hospital, Lancashire

Kent County Lunatic Asylum, Barming Heath, near Maidstone.—Fourth Assistant Medical Officer and Pathologist for two years; unmarried. Salary £175 per annum, rising £5 a year, with furnished quarters, attendance, coal, gas, garden produce, and washing. Applications to the Superintendent, Barming Heath Asylum, Maidstone.

Liverpool School of Tropical Diseases in connexion with University College, Liverpool, and the Liverpool Royal Southern Hospital.—Lecturer in Tropical Diseases. Salary £250 a year and proportion of students' fees, with the right of private practice, will be granted. Applications to Professor Boyce, University College, Liverpool.

Miller Hospital and Royal Kent Dispensary, Greenwich-road, S.E.—Junior Resident Medical Officer for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.

Morpeth Dispensary, Beechfield, Morpeth.—House Surgeon, unmarried. Salary £120 per annum, with furnished rooms, coal, and gas.

National Orthopædic Hospital, 234, Great Portland-street, London.—Surgeon's Registrar.

Norfolk and Norwich Hospital, Norwich.—Assistant to House Surgeon for six months. Honorarium £20, with board, lodging, and washing.

North London Hospital for Consumption and Diseases of the Chest, Mount Vernon, Hampstead.—Resident Medical Officer for one year. Applications to the Secretary, Offices, 41, Fitzroy-square, W.

Parish of Lambeth.—Medical Officer for District No. 6 and also a Medical Officer for District No. 8 of the Parish. Salary for No. 6 District £90 per year and for No. 8 District £80 per year, with extra fees as specified in the Orders of the Poor-law Board, subject to statutory deduction. Applications to the Clerk, Guardians' Offices, Brook-street, Kennington-road, S.E.

Royal Berks Hospital, Reading.—Assistant Medical Officer, for six months. Board, lodging, and washing provided and an honorarium of 10 guineas awarded conditionally.

Royal London Ophthalmic Hospital, Moorfields, E.C. Physician.

Royal Surrey County Hospital, Guildford.—Resident House Surgeon. Salary £80, with board, residence, and laundry. Also Assistant House Surgeon. Salary £30, with board, residence, and laundry.

Sheffield Union.—Assistant Medical Officer (single or widower), to reside at the Union Workhouse, Fir Vale, Pitsmoor, for twelve months. Salary £100 per annum, with apartments, rations, and other usual allowances. Also Junior Assistant Medical Officer for the Workhouse Infirmary, Fir Vale, Sheffield, for six months, unmarried. Furnished apartments, board, and washing provided. Honorarium of £12 will be granted. Applications to the Clerk to the Guardians, Union Offices, West Bar, Sheffield.

St. Mary's Children's Hospital, Plaistow, E.—Assistant Resident Medical Officer for six months. Salary at the rate of £50 per annum, with board, lodging, and washing.

St. Mark's Hospital for Fistula and other Diseases of the Rectum, City-road, London.—House Surgeon. Salary £50 per annum, with board and lodging.

Queen Charlotte's Lying-in Hospital, Marylebone-road, London.—Assistant Resident Medical Officer, for four months. Salary at the rate of £50 per annum, with board, residence, and washing.

University of St. Andrews.—External Examiner for Graduation in the Subject of Public Health.

West Bromwich District Hospital.—Resident Assistant House Surgeon for six months. Board, lodging, and washing provided. Gratuity £20.

Births, Marriages, and Deaths.

BIRTHS.

Brackenbury.—On Jan. 27th, at Stapleton-hall-road, Stroud-green, the wife of Henry B. Brackenbury, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

Griffith.—On Jan. 27th, at Park-square, Leeds, the wife of T. Wardrop Griffith, M.D., of a son.

Morris.—On Jan. 27th, at Gordon Lodge, Charlton-road, Blackheath, the wife of Clarke Morris, M.R.C.S. Eng., of a son.

Wilson.—On Jan. 28th, at Malvern, Kenley, the wife of Norman O. Wilson, F.R.C.S., of a daughter.

MARRIAGES.

De Lessert—Robberds.—On Jan. 25th, at St. Mary's, Arbroath, Alfred Alexander De Lessert, L.D.S., Union-street, Aberdeen, to Amy Caroline, only daughter of the late Rev. Frederick Robberds of Saltford, Somerset.

Walker—Moorhouse.—On Feb. 2nd, at St. Mary's, Crumpsall, Manchester, by Rev. R. Catterall, Rector, assisted by Rev. T. M. Macdonald, Rector of Kersal and Prebendary of Lincoln, Edward J. Walker, B.A., M.D., Manchester, youngest son of the late Rev. John Walker, Dublin, to Emily Henrietta, second daughter of Christopher Moorhouse, Fieldhead, Crumpsall, Manchester.

DEATHS.

Carless.—On Jan. 25th, at Devizes, suddenly, Edward Nicolls Carless, M.D., aged 50 years.

Crane.—On Jan. 25th, at Kensington-court-gardens, Samuel Leonard Crane, C.M.G., M.D.

Fisher.—On Jan. 30th, at his residence, Lowther-terrace, Lytham, Luke Fisher, M.D., aged 59 years.

Knight.—On Jan. 27th, at the Parsonage, Rainham, Kent, John Sladen Knight, M.D., M.R.C.P., aged 78 years.

Paul.—On Jan. 29th, at The Terrace, Camberwell, John Hayball Paul, aged 83 years.

Tiley.—On Jan. 25th, 1899, at Fleetwood, Lancs., William George Tiley, M.R.C.S., aged 79.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3 30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9 30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat (2 P.M.).

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1 30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College, (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9 30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3 30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's, (3.30 P.M.), Guy's (1 30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2. 30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (11th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1 30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (6th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square).—7 P.M. Council Meeting. 8 P.M. Paper:—Dr. W. Hunter: The Relation of *Dental Diseases* to General Diseases. Casual Communications:—Mr. L. Matheson: Some Obtundents —Mr. W. Rushton: An Improved Arm rest.—Mr. T. Harris: Models showing Suppression *of Permanent Teeth*.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. S. West: Some of the Clinical Aspects of Granular Kidney. (Lettsomian Lecture) *Lecture I.—Syllabus. The importance of* the disease, as shown by its frequency and its fatality. More often overlooked than diagnosed. The pathological forms. All chronic Interstitial Nephritis *is not Granular Kidney*. The relation *of Granular Kidney* to Acute Nephritis must be proved by clinical evidence. The changes in the vessels must be distinguished from Atheroma. The relation *of Granular Kidney to* Gout and Lead *Poisoning. The early recog*nition important; possible by physical signs only. Hypertrophy of Heart, secondary, but may be caused by Atheroma. Thickened Arteries, common in young, what is its *significance? Arterial* Tension; peculiarities in Granular Kidney. High tension in the young is important, and may be one of the early signs of Granular Kidney.

SOCIETY OF ARTS.—8 P.M. Dr S Rideal: Bacterial Purification of Sewage. (Cantor Lecture.)

TUESDAY (7th).—PATHOLOGICAL SOCIETY OF LONDON (20, *Hanover*-square, W.)—Dr. G. F. Still: Congenital Hypertrophy of the Pylorus.—Mr. S G. Shattock: Dilatation of the Œsophagus.—Dr. W. S. L. Barlow. Dilatation of the Œsophagus.—Mr. S. Boyd: Alveolar Sarcoma of Rectum.—Dr. Rolleston: Carcinoma of Cardiac Orifice of the Stomach.—Dr. H M. Fletcher: Adenoma of Brunner's Glands —Dr. C. D. Green Umbilicus Polypus.—Dr. F. P. Weber: Diffuse Syphilitic Change in the Liver. Card Specimens —Dr. R. Cautley (2), Dr. M. Fletcher, Dr. Rolleston: Specimens of Congenital Hypertrophy of the Pylorus —Dr. L. Barlow: Gastric Carcinoma spreading up the Œsophagus —Mr. H. B. Hickman: Carcinoma supervening on Gastric Ulcer.—Dr P. Weber.

WEDNESDAY (8th).—HUNTERIAN SOCIETY.—8 P.M Annual General Meeting 8.30 P.M. Sir H. Beevor, Bart.: The Declension of Phthisis. (Annual Oration)

SOUTH-WEST LONDON MEDICAL SOCIETY (Stanley's, 235, Lavender-hill, Clapham Junction, S.W.).—8 P.M. *Dr. C. Arkle*: Some Points in the Treatment of Tuberculosis

THURSDAY (9th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W)—8 30 P.M Specimens will be shown by Dr. Bantock, Dr. Jellett, Dr. Snow, and Mr J. F. Jordan. Papers:—Prof. M. Robson: Complete Removal of the Sac in a Case of Extra-Uterine Gestation.—Dr. M. Lawrie: *Notes* on a Case of Extra-Uterine Pregnancy.

FRIDAY (10th).—HUNTERIAN SOCIETY.—7 P.M. Annual Dinner at the Café Monico.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.)—8 30 P.M. Papers:—Mr. W. G. Spencer Tuberculous Cavities in the Lungs giving rise to Gaseous *Metastatic Abscesses.—Dr. Barlow* and *Dr.* Batten: A Case of Myopathy, with Autopsy, in a Boy of five years (illustrated by microscopical specimens and lantern slides)—Mr. J. R. Lunn: *Some* Results of Operation for Enlarged Prostate.—Mr. H. Betham Robinson: Hydatid Cysts of the Upper Lobe of the Right Lung and Liver Successfully Removed.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (6th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. L. Hill: Researches on the Influence of Gravity on the Circulation.

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. *General Monthly* Meeting.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: The Examination of the Thoracic Viscera.

TUESDAY (7th). — WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Dr. F. Beach: *Cases of General Paralysis of the Insane and Allied Disorders*

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 30 P.M. Dr. Beevor: On the Actions of Muscles.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. *Prof.* E. Ray Lankester: The Morphology of the Mollusca.

WEDNESDAY (8th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. L. Hill: Researches on the Influence of Gravity on the Circulation.

EVELINA HOSPITAL (Southwark-bridge-road, S E).—4 30 P.M. Dr. W. S. Fenwick: Clinical Demonstration on Vomiting in Infancy and Childhood. (Post-Graduate Course).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Fowler: Influence of other Diseases upon Pulmonary Tuberculosis.

THURSDAY (9th).—CHARING-CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Demonstration of Surgical Cases. (Post-Graduate Class.)

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Dr. A. Macfadyen: Toxins and Antitoxins.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: The Examination of the Thoracic Viscera.

FRIDAY (10th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. L. Hill: Researches on the Influence of Gravity on the Circulation.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1898, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 6d.

To be obtained *on ap*[illegible] the Manager, accompanied by remittance.

TO GOVERN MEDICAL PRACTITIONERS.

"Submit yourself to governors," said that most human and lovable of the apostles, Peter; but he meant to imply by governors duly constituted authority and not irresponsible tyranny or idle arrogance. To give way to either of these is to wrong ourselves and our neighbours. For which reason the following scheme is one that should be strenuously resisted by all the medical practitioners concerned and not only by them but by all the profession of the country who should unanimously declare that for medical men to work upon such a basis is cramping to their science, derogatory to their position, and totally impossible from every point of view.

COPY OF SCHEME INTRODUCED BY JOHN THOMAS, MINERS' AGENT, GARW MINERS' ASSOCIATION.

A Scheme to govern the Medical Practitioners of the Garw Valley, to be called the "Medical Practitioners' Governing Committee."

1.—The committee to be called "The Medical Practitioners' Governing Committee."

2.—The committee shall be constituted of one for every 100 workmen in each colliery involved in the Garw Valley district and shall be appointed by the workmen at a meeting duly called for that purpose.

3.—The duty of the committee shall be to appoint a sufficient number of qualified medical practitioners for the whole district, including Blaengarw, Pontycymmer, Pontyrhyl, Bettws, Coytrehane, Tondu, Brynmenuin, and Bryncethin.

4.—To receive all monies kept as poundage at the colliery offices.

5.—To pay the medical practitioners such annual salaries, with or without surgical appliances and drugs, as they think fit.

6.—That the committee shall have power to grant the medical practitioners one month holidays annually, either in the months of July or August, or as may be agreed upon between them.

7.—The committee to have power to appoint qualified Assistants to attend upon the workmen and their families during such holidays.

8.—The committee to pay the medical practitioners their salaries once every three months.

9.—The committee to have full power to deal with any emergency which may arise between them and the medical practitioners engaged by them.

10.—The committee to receive and give three months' notice to terminate all engagements between them and the medical practitioners.

11.—The medical practitioners to *be under the sole control of the Governing Committee* and to devote the whole of their time to attend upon the workmen and their families in all cases of accidents and sickness, including confinements.

12.—They shall render all assistance possible to obtain compensation to all injured workmen.

13.—They shall attend all committee meetings called for the purpose of discussing cases of injury.

14.—The committee shall issue an annual balance sheet, showing the state of the funds.

(1) It was a pretty taste in the author of this scheme to christen it a scheme to "govern the medical practitioners." The persons who subsist on the wages of their fellows and who give them orders to strike, to resume work, or to contribute to other strikes and who generally organise labour—finding perhaps the duties both less onerous and more remunerative than labouring—are apt to drop into a domineering tone; hence we may assume without much fear that the scheme leapt from the brain of a miners' agent.

(2 and 3) With Clauses 2 and 3 we have no fault to find. The miners ought to have a voice in choosing their medical attendant and ought to feel certain that the supply of medical men is adequate, for they require medical services too often not to value them highly.

(4) This clause might at some time possibly conceal a fraud upon both the medical men and the miners. Under it the "governing committee" might charge the men one rate of poundage and pay the practitioner at another and lower rate. The balance thus obtained would have a tendency to be spent in secretarial expenses, as everyone knows who has followed the practices of organisers in the interests of labour.

(5) This clause would regularise such a fraud as is suggested in the preceding clause.

(6) The time for the medical man to take a holiday is when the cases on his hands allow him to do so. And even if this were not the obvious case it is difficult to understand why the person who ministers to the bodily needs of the miners should not be as much a free agent with regard to his holidays as any gentleman who sells them beer or beef. Of course a competent substitute must be provided.

(7) It is not very long since the miners in a Welsh district made a demonstration in favour of an unqualified man who was dismissed by his employer because of the new regulations of the General Medical Council. This committee of laymen, and possibly not of highly educated laymen, must understand that the word "qualified" has a technical meaning. It does not mean a person whom the committee think suitable; but it means a man who possesses certain degrees and diplomas.

(8) On this clause and on Clauses 10 and 14 we make no comment.

(9) Medical men serving under a committee will, of course, take care to be provided with a proper legal agreement in which the duties of the parties towards each other are specified and in which provision is made for settling any disputes. The committee should only have—and, for that matter, should only be found asking for—such discretion as a fair agreement would give them. These remarks also hold good for Clause 11.

If Clauses 12 and 13 mean anything they mean that whenever a miner sees a chance of getting an annuity out of an owner the medical practitioner must help him whatever be the legal and medical merits of the case. Need we say that no self-respecting medical man would subscribe to such a condition and that its proposal stamps the scheme as immoral.

"INDISCRIMINATE MEDICAL CHARITY": A DISCLAIMER.

To the Editors of The Lancet

Sirs,—My attention has been drawn to an article in The Lancet in which a whole column is devoted to a lecture written for my special edification. It is really a work of supererogation on your part to fill so much of your valuable space for such a needless purpose, particularly as I have been a regular reader of The Lancet for over 12 years and have consistently followed its teaching on all matters of professional conduct. Regarding the circular from which you quote and on which your correspondent waxes so eloquent, I was quite oblivious of its existence until Sunday last when I heard of the comments which had been made by you on my want of respect for the dignity of the profession and on inquiry I learned that a circular had been issued setting forth the advantages of the Church Lads' Brigade, an organisation which has been of incalculable benefit to the boys of the district. The gentleman who was responsible for the publication of the circular then told me of its contents and said that a professional brother had objected to its being sent round. Immediately all further issue was stopped and there, it was thought, the matter ended. Indeed, the gentleman in question did not previously think to mention the incident to me, so that you see I was not in any way cognisant of the offending paragraph.

Now respecting your comments, they altogether exaggerate the importance of the matter. Instead of offering free attendance to "all sorts of persons indiscriminately," my connexion with the Brigade merely necessitates the medical supervision of 40 or 50 lads, to which number the company is limited. Then again your advice to me to find out the wages or the income of the lads' parents is quite unnecessary considering that in the majority of cases the lads' parents were known to me professionally before the introduction of the Brigade to this parish. As a matter of fact I have made a charge in all cases where they could afford to pay. I can understand, however, how the impression arose that I made no charge, seeing that in most of the cases the troubles about which I have been consulted arose from decayed teeth and these I have advised the lads either to have extracted or stopped by a dentist without, of course, taking any fee for that advice.

It is gratifying to learn that you exonerate me from any suspicion of unprofessional conduct even on *ex parte* evidence. I cannot help, however, coming to the conclusion that the individual who instigated the correspondence instead of first communicating with me direct was guilty not only of unprofessional conduct, but of a distinctly unfriendly act, and one unworthy of an Englishman and a gentleman. Trusting you will find space for this explanation and thanking you in anticipation,

I am, Sirs, yours faithfully,
R. J. Ferguson, M.D., M.Ch. R.U.I.

Thornton Heath, Feb. 1st, 1899.

WANTED A SUGGESTION FOR TREATMENT.

To the Editors of The Lancet.

Sirs,—I should be much obliged if any of your readers could help me in the following case. A lady asks my opinion if anything can be done to prevent her daughter, who is now only 16 years of age and over 5 ft. 10½ in. in height, still going on growing. Her friends have suggested gin as a remedy. Is there any medical or other authority for its use under such circumstances? The young lady is of prepossessing appearance, but her continued growth is looked upon as a calamity.

I am, Sirs, yours faithfully,
W. S.

Jan. 26th, 1899.

*** There is no evidence that gin possesses any particularly stunting effect, and to administer it for that purpose would be little short of criminal. The young lady and her friends must reconcile themselves to the stature which nature has granted to her. The only therapeutic measure which has been brought to our attention is contained in "Alice in Wonderland," not a sufficiently serious medical authority.—Ed. L.

A QUESTION OF FEES.

To the Editors of The Lancet.

Sirs,—I would be much obliged for your opinion on the following county-court case. I agreed to attend a Mrs. Glanville in her confinement for the small fee of 10s. 6d. provided that the fee was paid before attendance. On May 25th last she was attended in her confinement by my assistant, Mr. J. D. E. Williams, a legally qualified practitioner, but the fee was not forthcoming. I accordingly took out a county-court summons against Mr. Glanville for the ordinary confinement fee of 20s., as the fee of 10s. 6d. had not been paid according to agreement. The hearing took place this morning before Judge French at the Shoreditch County-court and the facts were not disputed, but the judge held that I could not recover any fee as 'I had not myself attended the woman' and gave judgment for defendant with 5s. costs." I may add that there was no neglect r anything whatever alleged against my assistant's conduct or n his attendance on the case. But the defendant alleged that the eason I did not attend was because I was drunk, which was a leliberate falsehood as I could easily prove it to be, and the judge tated that he did not believe that there was any truth in it. In order o reopen the case I propose to get Mr. Williams when he returns to London—as he left me several months ago—to take out a summons gainst Mr. Glanville for 20s. either in his own name or in our joint names, as I feel sure the judgment is wrong in point of law. If it is correct then no one can recover fees for services rendered by qualified assistants.

I am, Sirs, yours faithfully,
Pitfield-street, N., Jan. 31st, 1899. CHARLES W. J. DUNLOP.

*** In our opinion the decision is wrong. The principal is the right person to sue for the fees due to him in return for work done by his agent.—ED. L.

"THE STYLE OF PHYSICIAN."

To the Editors of THE LANCET.

SIRS,—The recent ruling as to the title of "physician" has somewhat cleared the air, but the subject of medical titles is still a little misty. The apothecary cannot legally describe himself either as "physician" or "surgeon," and I suppose he must in future be known as "Licentiate in Medicine, Surgery, and Midwifery of the Apothecaries' Society." This seems rather awkward and the natural remedy would seem to be union with the Royal Colleges. We are still in doubt as to the right of the M.D. to use the title of "physician" unless he is associated with one of the Royal Colleges and also whether it is allowable for one who has the legal title of "physician" to use that of "Dr." I believe that at present there is a perfectly honest difference of opinion on these two points which can only be settled by a friendly legal action or by an authoritative ruling by the General Medical Council. I think there are very few medical men who would wilfully assume false titles and it is certainly desirable that the matter should be settled. Perhaps I may venture to remark that I look upon the giving the courtesy title of "Dr." to M.B.'s as inconsistent with the position taken by THE LANCET. Either it is given because the M.B. is a physician in the eye of the law, in which case the diplomate of a physicians' college is also entitled to it, or it is a pure courtesy title which we understood THE LANCET did not approve. Hoping we may soon know where we are,

I am, Sirs, yours faithfully,
Loughborough, Jan. 28th 1899. J. B. PIKE.

To the Editors of THE LANCET.

SIRS,—Now that the case of Hunter *v.* Clare is finally settled would you through the columns of THE LANCET kindly inform us "what an L.S.A. may have inscribed on his plate," because in all fairness to the profession the same objection must hold good to an M.R.C.S., and L.R.C.P., yet at the same time there are hundreds of men with Scotch and Irish qualifications who are allowed to style themselves "Dr.?" As far as my experience goes 99 per cent. of the human race look upon a general practitioner as a man who is capable of dealing with both medical and surgical cases; therefore he is a physician and surgeon and if he be not allowed to describe himself as such will the General Medical Council give a title to all members of the profession who do not hold an M.D., F.R.C.P., or F.R.C.S. degree? There are many men who from love of the profession have started as unqualified assistants and have worked hard and paid their own fees, &c., in order to get qualified and at the same time know their work quite as well as men holding the highest degrees it is possible to obtain. I have on more than one occasion in the States amputated and operated for strangulated hernia with onl a miner to give chloroform, yet at the same time, being only an L.S.A., I, according to the late decision, am not allowed to call yself "physician and surgeon."—I am, Sirs, yours faithfully,
Jan. 30th, 1899. AN L.S.A.

SALINE ENEMA IN HÆMORRHAGE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 21st, p. 190, Mr. Gabriel asks if saline enemas have been used in typhoid hæmorrhage. A large number of cases are noted in Sections 152-4 of the Medical Digest and Appendix where the effects of such treatment were most beneficial in hæmorrhagic collapse from various causes.

I am, Sirs, yours faithfully,
Finchley-road, Hampstead, N.W. RICHARD NEALE, M.D. Lond.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—My attention has been called to an article in the *Daily Mail* in which my name is mentioned. I can only say that this has been done absolutely without my knowledge or sanction either direct or indirect.

I am, Sirs, yours faithfully,
W. S. HEDLEY.
Mansfield-street, Portland-place, W., Jan. 31st, 1899.

WANTED A HOME.

A CORRESPONDENT writes to inquire if any of our readers can put him in communication with someone who will receive in an institution or suitable home a young man, aged 22 years, suffering from St. Vitus's dance. The terms must be moderate.

UNSEEMLY PRACTICES.

To the Editors of THE LANCET.

SIRS,—X has a practice in the suburb of A, where he also holds a medical aid appointment. He accepts a similar appointment in another suburb of A (which has been refused by the medical men in that district), starts a branch practice there, works it for a year, then sells it to Y, who carries on the practice on the same lines as X—viz., by touts importuning weekly from door to door irrespectively of refusal and whether a medical man is in immediate attendance. This weekly canvas goes on to join Doctor Y's club. Is not such conduct a gross breach of professional etiquette on the part of X and Y? Cannot the General Medical Council legislate in such cases if brought to their notice? The legal profession has its remedies, why should not we? Bakers and butchers are above door-to-door soliciting and underselling. I think it time a move were made—more so now, as the next meeting of the General Medical Council intends dealing with the question of medical aids in general—and Mr. Victor Horsley appealed to, who before his election promised us his support in this direction.

I am, Sirs, yours faithfully,
Jan. 28th, 1899. SPES.

*** The behaviour of X and Y as reported by our correspondent is unprofessional, but the General Medical Council has at present no power to "legislate," and we doubt whether the proceedings of X and Y would be considered "infamous in a professional respect."—ED. L.

"WANTED A 'WEIR-MITCHELL INSTITUTION.'"

To the Editors of THE LANCET.

SIRS,—If "Nemo," writing in THE LANCET of Jan. 28th, will communicate with me stating the nature of the case and the amount of outlay desired I think I can help him.

I am, Sirs, yours faithfully,
J. LIONEL STRETTON.
27, Church-street, Kidderminster, Jan. 30th, 1899.

To the Editors of THE LANCET.

SIRS,—In answer to "Nemo" in THE LANCET of Jan. 28th, p. 277, I can say that Dr. A. S. Eccles has such an institution in his own house. I have been myself under his care with the best results for the consequences of overwork.

I am, Sirs, yours faithfully,
Geneva, Jan. 30th, 1899. A. CORDES, M.D.

◆

Oculus.—Mr. F. Davidson, 20, Great Portland-street, sells a good little book under the inelegant title "Sight-testing for the G. P.," which covers the ground suggested.

Sebaceous.—We have no record of the composition of the article in question.

R. J.—We recommend application to the Dean of the Medical School.

Auctor.—We certainly do not consider such a book to be needed.

J. W. W.—Sulphate of soda, quinine, and iron.

ABSTRACT OF THE

Lettsomian Lectures

ON

SOME OF THE CLINICAL ASPECTS OF GRANULAR KIDNEY.

Delivered before the Medical Society of London

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL, &C.

LECTURE I.[1]

Delivered on Feb. 6th, 1899.

GENTLEMEN,—Granular kidney is a disease of great importance on account of its frequency—a frequency which is by no means adequately recognised. Post mortem it is often discovered when not suspected. It is often in itself a cause of death, even of sudden death, and it often explains why death has happened in other diseases which otherwise might not have proved fatal. During life it is often discovered unexpectedly if looked for, it is often overlooked if not suspected, and it often explains a case which has been a puzzle until granular kidney gave the key. For all these reasons granular kidney is not only one of the most interesting of diseases but also one of the most important. The general frequency of granular kidney post mortem ranges from 13 2 to 18 per cent., so that it is a very common condition. Nothing will better prove the importance of granular kidney than the following statistics obtained for me by Mr. Horder, the result of an investigation made into the cause of death in persons brought into St. Bartholomew's Hospital dead or dying. The total number of such cases (excluding children under five years of age) was 79, in all of which a post-mortem examination was made. Of these 64 were dead on reaching the hospital and 15 died in the surgery. In 48 per cent. of these cases chronic interstitial nephritis was present, in 16·8 per cent. it was the only cause of death, and in 12 6 per cent. more it played its part either in producing death or in causing the lesion which led to death—i e., it was the sole or part cause of death in 38 4 per cent. Nothing more is necessary to prove the importance and frequency of the disease. Of the remaining cases three patients had phthisis and one had pneumonia.

The influence of granular kidney upon the prognosis of other diseases may be well illustrated by the case of acute pneumonia. In 100 fatal cases which I investigated 23 showed some pre-existent chronic disease of the lungs or pleura, eight of the heart, and 10 of the kidneys.

Granular kidney is a bilateral and to a great extent symmetrical affection—that is to say, both kidneys are affected, though not necessarily to the same extent. The difference in weight, however, if there be any, is slight and rarely exceeds an ounce. The kidneys may be much contracted and greatly reduced in size, so that they may not weigh more than one and a half ounces or two ounces each. Extreme contraction such as this is really rare. The kidneys are, it is true, usually reduced in size and weight, by no means to the extent which seems generally believed, while in some instances so far from being smaller than normal they may be much above the average size and weight. In other words, there are large as well as small granular kidneys, just as there are large and small cirrhotic livers. The kidneys, moreover, are not always granular on the surface, though microscopically the interstitial change may be marked enough.

The typical granular kidney is small, contracted, hard, cirrhotic, or granular, has a nodular surface, often studded with numerous cysts. On section the whole kidney is found to be cirrhotic and wasted, but the wasting affects chiefly the cortical region. The changes consist in fibroid induration and cellular degeneration. Though often described as chronic interstitial nephritis it is an open question h far these changes are in reality of inflammatory orig Certainly in most cases we have no more evidence of infla matory processes in the cirrhotic kidney than we have the cirrhotic liver.

Granular kidneys are sometimes described as of two kin the white and the red, and the difference in colour is h by many to denote difference in origin and they are accor ingly called the contracted white and the contracted re The small white is stated to be generally somewhat larg than the red, to be less granular on the surface, and to ha more cells left, these cells being in a condition of fat change, to which the colour is referred. These statemen are not in my experience correct, for small white kidne are often quite as small and as granular on the surfa as the small red and may have quite as few or ev fewer cells left and these cells are often not fatt The two forms certainly exist. The term "contracte white" introduces confusion and seems to assume th which ought to be proved—viz., the different origin the two forms. It suggests that the small white is b the later stage of the large white kidney. It assum that every stage can be demonstrated between the larg white kidney of chronic parenchymatous nephritis throug the contracting white to the contracted white If this w the usual sequence of events it ought to be capable of eas clinical proof. Pathologically it is easy to show that chron parenchymatous or the large white kidney presents interstitial changes of a contracting kind, but the weak link in th chain is between the so-called contracting form and the contracted form. If the distinction between the two forms to be made it would be very much better to speak of the as small white and small red or as white cirrhotic and re cirrhotic rather than white and red contracted kidneys. Fo myself I consider the difference to be really one of colou chiefly. Microscopically I do not see that any clear distinction can be drawn. If pathologically the distinctio between the two forms is open to question, clinically, so fa as I can see, no distinction at all can be drawn betwee them—that is to say, with exactly the same clinical symptoms we may find the kidneys in the one case white and i the other case red.

Granular kidney is often described as chronic interstitia nephritis but all forms of chronic interstitial nephriti are not necessarily granular kidney. First of all must b cut out of the category of granular kidney all those cases i which the lesion is unilateral—for example, that which results from obstruction to the ureters. Again, al cases of patchy fibrosis—e.g., the results of infarcts o gummata, even if both kidneys are involved—must b excluded, for they do not produce the clinical symptoms of granular kidney. Even when the lesions are bilateral and both kidneys are affected I should still exclude from the category of granular kidney certain forms of chronic interstitial nephritis which are often included pathologically, though clinically they are distinct. I refer to the degenerate kidneys met with in connexion with advanced atheromatous disease or with the chronic gout of elderly persons—in fact, the kidneys which are commonly called *senile or gouty*. These kidneys are often markedly interstitial and there is a good deal of fatty and cellular degeneration giving the surface a mottled appearance, but they need not necessarily be granular and are usually large. Moreover, the cases need not run the clinical course of granular kidney. Eliminating these various forms we are left with a pathological group of cases of interstitial nephritis of a definite character which we commonly recognise by the terms "granular" or "cirrhotic" kidneys.

In most recent writings granular kidney is divided into two forms, the arterio-sclerotic and the renal, and these are often dealt with in different places, the one form under diseases of the vessels, the other under diseases of the kidney, so that in order to gain a complete view of granular kidney as a disease it has to be read in different chapters. This is very inconvenient and confusing and suggests a marked difference between the two forms which clinically does not exist. It has, however, one advantage in that it fixes attention upon the question which is still at issue—viz., whether it is in the vessels or in the kidney itself that the primary causes of the disease are to be sought.

Acute nephritis attacks the cells primarily and chiefly, but the interstitial tissues are always involved to some extent and the more so the longer the disease has existed. This small-celled infiltration may in time end in the production of connective tissue at first in part only, in other cases more widely

---

[1] Lectures II and III. will be delivered on Feb. 20th and March 6th, 1899, respectively.

No. 3937.

distributed, and there will be the more of it the longer the disease has lasted. The large red kidney of acute nephritis passes as the disease lasts gradually into the large white. In the large white kidney some interstitial change is often found—sometimes local, at other times more diffuse; and admitting that pathological connective tissue contracts in the kidney as elsewhere we should expect the large white kidney in time to become smaller, to undergo a certain degree of contraction in parts if not as a whole, and of this we have frequent pathological proof. The kidney is then described as "contracting white." It is even conceivable theoretically that the contraction might go much further, so that in time we might have the large white kidney passing into what may be described as a small white kidney or even possibly ending in a small red kidney.

Now, admitting the pathological possibility that acute parenchymatous nephritis might end in a granular kidney, if this actually occurred frequently it ought to be capable of easy clinical proof, for the symptoms of acute nephritis are not such as are likely to be often overlooked by the patient or by the friends of the patient. Such cases are recorded; but they are certainly rare, and many of them prove on careful critical investigation not to be so conclusive as they at first sight appear. I have been on the watch for them for years, and although I have seen many in which the lesion has gone so far as to produce a somewhat diminished white kidney, the majority of such kidneys are still much above normal size. I have never traced a single case beyond this—i.e., as far as a small white kidney. I do not say that it does not occur; on the contrary, I believe it may. I merely say that so far I have failed to observe it. It might be urged that marked contraction in granular kidney would be more frequent if the patients lived long enough. But it does not necessarily follow even when the symptoms of chronic parenchymatous nephritis have lasted for many years that a contracted kidney will result. I know of a woman who has had several attacks of parenchymatous nephritis in the course of 13 years and who has never at any time lost the albumin from the urine; yet now, at the end of 13 years, her arteries are thin and her heart is not hypertrophied, she appears to be in fair health and her retinæ are normal, and there are, in fact, in spite of the long duration of the case, no clinical signs whatever which would justify the diagnosis of granular kidney. Nor can any closer relation be proved by the clinical history to exist between granular kidney and antecedent acute nephritis. It is quite unusual in cases of granular kidney to obtain any history of symptoms which would in any way justify the diagnosis of acute nephritis. This fact has been always insisted on as long as granular kidney has been recognised as a disease and it is generally accepted. Even when the history of antecedent acute nephritis is obtained it does not necessarily follow that the granular kidney has been the result of it. The occurrence of acute nephritis is no proof in itself that prior to the acute nephritis the kidney was sound or, in other words, that if after an attack of acute nephritis the kidneys are found granular they became granular as the result of the acute attack. For, on the one hand, it is not uncommon in the course of a case already recognised as one of granular kidney to see acute parenchymatous nephritis develop, and, on the other, to see a patient hitherto believed to be healthy with the symptoms of acute parenchymatous nephritis, and yet for that patient to present thickened arteries and even eye-changes which show that the disease really dated long before the commencement of the so-called acute attack—in other words, that the patient has got acute nephritis in both cases alike because the kidneys were already diseased. Indeed, I think we may almost go so far as to say that as in children acute parenchymatous nephritis raises a strong presumption in favour of a recent attack of scarlet fever, so in the adult it ought to suggest the suspicion that the kidneys were previously unsound—in other words, granular. Of this I am quite sure that if in cases of acute nephritis in the adult the signs of granular kidney be looked for they will very frequently be found. If, then, in spite of the fact that in the majority of cases of granular kidney the history and symptoms of nephritis are lacking, granular kidney is still to be referred to some antecedent nephritis, it follows that the initial attack must either have been slight and therefore overlooked or else that it was of some peculiar and specially latent kind.

It is evident from what has been said that i only in a very small number of cases that a history of ant ent acute nephritis can be obtained; that in still fewer can a case be traced from an initial acute nephritis to granular kidney. It follows, therefore, that most cases of granular kidney must be referred to some other origin.

W. H. Sr
lver
epartm

The changes in the arteries with granular kidney are general, widespread, in fact universal, throughout the whole body. They are found in all parts alike, in the kidney, for instance, as well as in the brain, the eye, the spinal cord, or even the skin. Now, there are only two forms of general arterial change recognised in pathology—viz., atheroma and that connected with granular kidney. Atheroma is a well-marked disease of the vessels. It is the degeneration which is usual as age advances, and though sometimes met with in earlier life and sometimes even in quite young people it is certainly a comparatively rare affection at the time when the changes of granular kidney are most common. Atheroma being a general disease will, of course, affect the renal arteries like any other and will produce in the kidneys similar changes to those to which it leads in other cellular organs—e.g., in the brain. Thus it is not at all uncommon in the later periods of life to find the kidneys large and mottled, showing a good deal of interstitial tissue and of cellular change, yet these atheromatous or senile changes do not as a rule, though they may sometimes, lead to the well-known granular contracted kidney. Of course, old persons may suffer from granular kidney and the two conditions may be associated. But for all that if the question be regarded without bias and in a general comprehensive way it must be acknowledged that atheromatous diseases of the arteries and the changes of granular kidney are different in kind as well as in history. In granular kidney the thickening of the vessels is fairly uniform, at any rate it does not occur in the irregular patches of atheroma, and is universal. As to the exact nature of the change in the vessels opinions still differ as they have done from the first. There can be no doubt that there is a considerable amount of muscular hypertrophy in the vessels or that it is associated in many cases with changes in the intima as well as in the adventitia, which are not atheromatous, and yet are of a marked character.

The relation between the cardio-vascular and the renal lesions is very difficult to determine. So far as the cardiovascular symptoms go I think we may say this—that the cardiac lesions being of the nature of hypertrophy must, as in other cases, be the response of the heart to some extra work thrown upon it of a permanent kind; it must therefore be secondary. It certainly seems more probable that both the heart and the vessels hypertrophy together for the purpose of assisting the circulation to overcome some obstruction. If this be so the obstruction must be peripherally seated and must be sought therefore in the small peripheral arteries or capillaries. In these peripheral vessels the possible causes of obstruction are two: either there must be a structural change—that is to say, an anatomical lesion—or some functional disturbance which interferes with the passage of the circulation through the vessels. If the change be structural and the lesions of the peripheral vessels are of a degenerative character, being general throughout the whole of the body they would involve the kidneys as well as other parts and in this way it is conceivable that the kidney disease might be a coördinate or subordinate part of the general vascular disease. This is a theory which is now indicated by the term "arterial-sclerosis" and such kidneys are described as "arteriosclerotic" kidneys.

If, on the other hand, the change here be not of a structural kind but a functional one, any structural change that is found being of a secondary and subsequent order, the obstruction must depend upon some impurity in the blood. But this impurity of the blood which renders it more or less obnoxious to the tissues may be either of a renal or extrarenal origin. If of extra-renal origin then the result may be the same as in the former case—viz., a general vascular disease which affects the kidney as well as other parts; but it may also be of a renal origin, in which case there must have been some renal mischief antecedent. Thus even from the point of view of the vessels we are brought back again to the two original views about which so much discussion has raged—viz., whether the disease is primarily arterial or primarily renal. If the changes in the vessels be regarded as primary, as they certainly are in atheroma and may be also in granular kidney, then it might be possible to find cases of marked changes in the vessels with little or no changes in the kidney. And the same would be true if the changes in the vessels and in the kidney both stood in relation to some common cause.

It is only by studying the beginnings of the disease—that is to say, granular kidney in its early stages—that we can hope to arrive at a solution of these difficulties for in the later stages all these changes are present together and it is difficult if not impossible, to form any opinion as to precedence of the one or the other. From whatever point of view then we regard granular kidney, whether pathological or clinical we come to the same conclusion—viz, that whether primarily arterial or primarily renal granular kidney is a disease *sui generis* and ought on that account to be treated in writing on the subject under a separate heading and not split up, as it generally is, between diseases of the arteries on the one hand and diseases of the kidneys on the other

Granular kidney is a very insidious disease For a long time it presents no symptoms at all and can be recognised then by physical signs alone The only definite symptom perhaps in the early stage (and even this is not constant) is an increased frequency of micturition especially at night, but as this has been of such gradual onset that the patient has become quite accustomed to it and does not regard it as peculiar no complaint is made of it unless it be extreme and the history of it is often only to be elicited on pointed questioning When symptoms arise the disease is already far advanced In other words the symptoms do not occur until late in the disease The symptoms fall like the lesions into groups—viz, "cardio vascular" and 'renal' Speaking generally, the cardio vascular are earlier than the renal The cardiac symptoms are those of heart failure more or less pronounced The vascular symptoms are the more or less mechanical effects of the vascular lesion and consist chiefly of hæmorrhage and its results The renal symptoms are the latest to develop and they fall into two groups according as they are of gradual development or of sudden onset and they are frequently described as chronic and acute uræmia respectively I should prefer to call them acute and chronic renal toxæmia Both alike are to be connected with the wasting in the kidney and its consequent defective action The gradual and progressive wasting is attended with the gradual and progressive development of the chronic form of uræmia "Renal cachexia" is the name which I should prefer to give to chronic uræmia It strongly resembles, both in character and course the cachexia which is seen in a variety of other diseases—e g, in Addison's disease in the later stages of cirrhosis hepatitis in diabetes and in malignant disease It consists in a gradually increasing anæmia and asthenia associated with various miscellaneous symptoms The symptoms in all these cases are similar, but differ from those which are usually described as acute uræmia and the difference is probably not one of degree only but of kind so that I think they ought to be distinguished by different names For the first I should reserve the term 'renal cachexia' and for the second I should use that term which is generally accepted—viz "uræmia and both alike, both the cachexia and the uræmia may be of slow or sudden development

I propose to deal with the signs and symptoms of the disease in this order (1) the physical signs, (2) the cardio vascular symptoms and (3) the renal symptoms It is the early signs of the disease rather than the late symptoms which are of importance What is required is an early diagnosis before the disease is far advanced and this is essential if light is to be thrown upon the causes and course of the disease or if influence upon it is to be successfully exerted upon it by treatment In the early stage the diagnosis is to be made by physical signs and not by symptoms

The physical signs are high tension and thickened arteries hypertrophy of the heart and albuminuria When these are all present together the diagnosis is easy even in the young and the diagnosis thus made during life is verified post mortem But if one or other of these physical signs is absent the question arises, Of what value are those remaining? For instance, if albumin is absent what do high tension and thickened arteries mean in the young? Or if the arteries are not thick or the tension high, but albumin be present, what is the significance of the albuminuria? Each of these questions is of great clinical importance We know that the vascular changes—viz, thickened arteries and high pulse tension—develop so early in the course of granular kidney that they seem to be rather coincident or as some maintain even antecedent phenomena than effects consequent upon and produced by the kidney lesion If this were so vascular changes might be found without the kidney lesion and such cases are described

Post-mortem evidence would point to hypertrophy of the heart as a most important sign of granular kidney and so it is in the later stages where the cardiac enlargement is such as to be easily made out by percussion In the early stages it is of very little assistance because of the difficulty in diagnosing it then. The hypertrophy of the heart is probably secondary to the vascular changes and the result of them and therefore not of the prime importance some are, or so likely to be met with early.

Thickening of the arteries is one of the cardinal signs of the disease and is never absent in advanced cases I have already referred to the fact that thickening of the arteries is by no means uncommon in young people and the question as to what its significance is becomes important in relation to the early signs of granular kidney Now, at this age the thickening cannot often be of an atheromatous nature for although atheroma does occur in early life it is very much rarer than is the thickening which I am speaking of The change is in great part muscular no doubt as it is in granular kidney and the effect of nitrite of amyl upon it is the same Arterial thickening always rouses my suspicion in young people and leads me to make a careful examination for other symptoms, sometimes they are found and the diagnosis is clear, but not unfrequently nothing else is found and the doubt remains as to the meaning of this thickening in relation to granular kidney, but that it is pathological there can be no question

In well marked—i e, advanced—granular kidney the high tension pulse as well as the thickened arteries are well recognised The tension is measured between the pulse waves, the arteries, therefore feel abnormally full as well as abnormally tense When the heart begins to fail the diminished force does not necessarily alter the character of the wave When the tension falls the fall is due to a failure of the artery and not necessarily of the heart at all though both may fail together The low tension then observed is a neuro paralytic phenomenon and a bad sign It occurs only in the later stages of the disease but may then continue for some time Though the tension be low the thickening of the arteries can still be easily made out and is as characteristic as ever A persistently high tension to whatever cause due is of itself pernicious but not so with granular kidney paradoxical as thus may seem The patient is best without granular kidneys but if the kidneys be granular it is better that the tension should be high rather than low; in other words the patient is worse with a low tension; and this explains the benefit of digitalis in such cases—it does so much good by raising the arterial tension This low arterial tension or rather the fall in tension in the later stages of granular kidney is of great clinical importance the value of which Sir William Broadbent has lately emphasised To one other phenomenon I may refer which though implied by what has just been said is not generally recognised although easy to be observed if looked for I refer to the irregular fluctuations in tension which take place in the later stages of the disease before the tension becomes persistently low Thus it may be felt to vary considerably even in very short spaces of time—even for instance while the finger is placed upon the pulse In the early stages of granular kidney, go back as far as we may, as soon as the disease is diagnosable the pulse tension is high and the artery is thickened The question arises What is the value of a high pulse tension in a person in whom there is not yet other evidence enough to diagnose granular kidney by? Temporary or transient increase of tension may occur in a variety of affections but it is not to these that I refer. I am dealing with those cases in which the tension is persistently raised Sir William Broadbent differing as he does from Mahomed in theory yet attaches quite as great significance to this increase of pulse tension He describes as the ultimate results of this increased tension a variety of symptoms cardiac failure general disturbances of health a sort of cachexia and even hæmorrhage which, as I stated, could be truly predicted long before it occurred These are of course the same symptoms as those produced by advanced granular kidney If the kidneys are not granular in these cases, of which no proof is given, the arteries must at any rate become diseased if hæmorrhage is to occ[illegible] it will [illegible] can hardly be asserted [illegible] which may be comprehended when I name the facts that our camp was in the open country, in a highly infected centre far removed from any town or decent water-supply, and in the midst of rebellious natives. Despite these drawbacks, however, a considerable amount of work was done and two methods of inoculation were devised—viz., glycerinated blood followed by virulent blood and the later method which has been so largely adopted in the colony—viz., the use of glycerinated bile followed by virulent blood. In the early part of the following year (1897) I broke up my camp and proceeded to the Victoria Compound at Kimberley where I prosecuted my work for a few weeks and then went down country, forming a temporary camp at Steynsburg for the purpose of supplying virulent blood to the various bile stations then being formed in the Midland and Eastern Provinces. Eventually, late in the year, I was enabled to proceed with my staff to the headquarters at the Institute in Grahamstown.

Among the earlier observations which I was enabled to make was the important one that the blood of animals suffering from rinderpest if kept nearly aseptic at the ordinary temperature begins to lose its virulence about the sixth day after withdrawal from the body. Animals inoculated with infected blood which had been kept for nine days did not contract the disease nor did they acquire immunity. Similarly the nasal mucus from a spontaneous case of rinderpest was found to lose its virulence very quickly if exposed to the air and kept for any period beyond 24 hours. It will be seen that the recognition of this attenuation of virulence by keeping is of the first importance when immunisation is being carried out by means of the bile of animals suffering from rinderpest. The blood of such animals can retain its virulence when quickly dried in a very thin layer, but if it is dried in a thick layer its virulence is destroyed. Thus it is seen that the danger of the spread of the disease from dried masses of material of rinderpest is not very great, but the almost invisible contact of clothes, boots, hands, &c., on which the virus is almost immediately dried forms the greatest and most insidious infective agent. It is unnecessary for me to discuss the whole of the experimental work carried out by my staff inasmuch as this is fully dealt with in my annual reports for the years 1896 and 1897, in the latter of which I have dealt with the subject *in extenso*. I propose at this time to confine myself to the systems of inoculation which have been more or less in vogue and to offer my own views as to the manner under which these act.

I have alluded to the fact that if the virulent blood of animals suffering from rinderpest is kept aseptically for a few days and then mixed with glycerine and kept for eight days its virulence becomes entirely lost. If, however, from 20 to 30 cubic centimetres are used for inoculation by subcutaneous injection into cattle one can inoculate the animals with 0·1 cubic centimetre of virulent blood 10 days later without setting up rinderpest. I have since determined that the plasma and the serum of this blood, even when passed through a Pasteur filter, can be used in this way and I am thus enabled to assert that in the serum of the blood of animals in a late stage of rinderpest there is present in a greater or less degree an immunising substance. When Dr. Koch had discovered the immunising property of fresh bile I determined to endeavour to ascertain whether such bile could not be used in respect to the supposed presence of an immunising substance, because I reasoned that if the blood contained it possibly the bile might also and in greater amount. If the bile were proved to contain it the collection for preparation of bile would be easier than in the case of blood, especially by untrained or unskilled hands. The experiments necessary for this investigation were carried out on a small scale at first and having given excellent results were then proved in the case of several herds, the first being one of 125 animals at Belmont. Since then the method has been almost solely used throughout the Eastern Province. In Cathcart it was entirely used except in the case of one or two herds in which infection had appeared and to which defibrinated salted blood was used as a curative agent although not always with success. Including, however, those animals which died as a result of being spontaneously infected the total loss for the district was only about six per cent. In Somerset East the mortality was six per cent. In two areas the mortality was higher owing to the presence of red-water; in others it was less, as for instance in the Winterberg, where out of 12,000 animals inoculated, many of which were inoculated with a second dose of virulent blood following upon the first, only about half-a-dozen animals died.

The immunity thus produced lasts for several months, but if after the first inoculation with virulent blood a second or even third is made with increasing doses the immunity is greatly increased and its period of duration is very greatly extended. In the case of Dr. Koch's method of inoculation in which fresh rinderpest bile is used immunity is produced as a rule and maintains itself for several months although in some instances its duration is much shorter. The Cape Colony owes a debt of gratitude to Dr. Koch for this most important discovery, which was the first real step towards protective inoculation and which, with the increased light that experience can give, will probably be made use of at future dates in other countries. Around this method controversy has been waged, and although I have hesitated hitherto to give too emphatic utterance to my convictions I feel that now that the public have got beyond the reach of panic I may in justice to myself place before my medical brethren the conclusions at which I long ago arrived.

It may be remembered that Dr. Turner and Dr. Kolle in a paper communicated to the *South African Medical Journal* asserted that after the inoculation of animals in an unaffected area with the bile of animals affected with rinderpest the disease could not follow as a result of that inoculation. Their reason for this statement was that they held "that the gall itself cannot communicate rinderpest" and they added that "this is a fact much to be regretted, because were this possible then the immunity conferred by the bile would be of much longer duration than it has been proved to be." Veterinary surgeons throughout South Africa as a result of their extended experience in the field are unanimously opposed to this view as they hold that in very many cases the disease is conferred by inoculation with fresh rinderpest bile. My own experience in the field and the experimental work carried out not only in the Institute but also in the Victoria Compound at Kimberley and elsewhere admits of my saying that bile can and does produce rinderpest but certain samples of bile do so more than others. It has to be remembered that the bile used for the Koch method is required to be a deep bottle-green-coloured bile with a white froth. I have found that if such a bile is used fresh it does not always produce rinderpest; but I have also found that in some cases such a bile may entirely fail to confer any immunity and my experience in this regard agrees with Dr. Koch's own utterances. On the other hand, when I have used discoloured bile, brownish, yellowish, or reddish *fresh*, it has almost invariably produced rinderpest in some of the animals inoculated.

In order therefore to arrive at an explanation of these facts let us return to Dr. Turner's paper. He states that Dr. Koch considered that bile acted in virtue of its containing "the organism in full activity but this activity was restrained by the presence in the bile of a chemical substance probably of an albuminoid nature." I fully concur in this view, but I hold that, in addition to the inhibiting substance bile also possesses a passive special immunising substance. Dr. Koch mixed slaughterhouse bile with virulent blood and thereafter inoculated animals without setting up rinderpest, but no immunity resulted from the inoculation. From this it is evident that the inhibiting substance is germicidal and is present in healthy bile. In my experience discoloured bile from animals suffering from rinderpest produces rinderpest if used fresh, hence I conclude that the inhibiting substance in the bile tends to disappear as the disease advances. In using glycerinated biles I have found that early brilliant-green biles possess very little immunising substance, but the deeply discoloured biles possess it in the greatest amount; hence for the preparation of glycerinated biles I prefer that which has begun to become altered in its colour.

From a consideration of the above conclusions it may be seen that the inhibiting and immunising substances of bile are usually present in an inverse ratio. Now, in the Kimberley Compound the biles selected were invariably early biles (biles which had not begun to alter) and in regard to these I should expect to find that on the inoculation of such biles rinderpest did not always follow. Moreover, I wish to emphasise my previous discovery that the virus tends to attenuate by keeping, and as this applies equally to bile I have kept virulent biles for a few days and inoculated them with safety. Now, it has to be remembered that the bile could not be kept in the field and hence it was used with the least possible delay. Here then lies the true explanation of the fact that rinderpest has been proved to follow inoculation with fresh bile. I fully concur with Dr. Krause in this respect.[1] Dr. Turner believed that glycerinated bile possessed only a feeble immunising power and he stated that when animals inoculated with it were 10 days later inoculated with 0 2 cubic centimetres of virulent blood 70 per cent. of these animals died. Seeing that Dr. Kolle inoculated 10 of my Belmont herd with virulent blood of his own selection and received from me at his urgent request permission to do so and moreover that not one of these ever showed the slightest illness as a result of this inoculation, and since this method has also been widely tested throughout the colony, it seems to me that Dr. Turner did not use glycerinated bile as I use it or as farmers have used it. A late rinderpest bile when glycerinated possesses a powerful passive immunising action. At the Sundays River estate the natives would not inoculate and an enormous mortality has ensued. The manager of the estate, Mr. Goldhawk, inoculated his own cattle, about 400, with glycerinated bile only, repeating it at intervals of one or two months and, although they were fully exposed to infection, not one of them became affected. None of these animals were inoculated with virulent blood. Were South Africa at a future date to become threatened by invasion of rinderpest from the North again I would strongly recommend that the bile from spontaneous cases dying within the area of infection should be used to produce glycerinated bile and that inoculation with this material should be proceeded with in a broad zone or belt well outside of the infected area so as to form a cordon of passively immunised animals and that within this area and gradually overtaking it inoculation should be carried out by Dr. Koch's method. By this means in a gradually extending circle, the infected area being the centre, all animals would be first inoculated with glycerinated bile which cannot possibly confer the disease and subsequently according to Dr. Koch's method with fresh bile. At the recent juncture it was impossible to start new bile stations and hence I concurred in having recourse to serum only, as there being then very little disease in the colony and serum being available in great quantity it was the cheapest way of dealing with any small outbreaks which might arise. At the same time I think it right to state that in any serum and blood inoculation the immunity produced is of the slightest and can be readily broken down in the presence of spontaneous infection unless during the course of inoculation a severe febrile reaction has been produced. In the earlier work with serum Dr. Turner and Dr. Kolle were convinced that serum could be readily used as a curative agent for herds in which spontaneous infection had appeared, and although I was strongly opposed to this view I was in the minority at the former conference. Extended experience has, however, now shown that where animals acquire the disease spontaneously and have not previously been inoculated with bile the effect of even very large serum inoculations is not very great, *so much so that the Colonial Veterinary Surgeon is now of opinion that the cheapest manner of dealing with such animals is to destroy them.* I have referred to mortality following upon rinderpest inoculation as being due in *some cases to the complication of red-water or "Texas fever."* I have dealt with this in a detailed *report.*[2] *Meanwhile, however, I may* state that if healthy cattle which have been running on a red-water veldt and through having been bred in the area are either salted or immune are used to be infected with the blood from animals infected with rinderpest they take the disease in all respects like other clean cattle. Examination of their blood may, and usually in my experience does, fail to show any red-water parasites; nevertheless, if susceptible animals are inoculated with such blood they develop both rinderpest and red-water and this simultaneously. Curiously enough the parasite in such circumstances varies from the form described and recognised, and forms smaller or larger, sometimes vacuolated, intra-globular parasites conforming to those described by Dr. Turner and Dr. Kollo as having appeared at the Kimberley Compound and among the cattle inoculated by the former at Robben Island. I have followed up the life-history of this form of the parasite and have shown that it eventually develops in susceptible animals into the well-known form of the "Texas fever" organism. It is liable to appear in inoculated animals whether after bile and blood or serum and blood and hence in all future inoculations from the blood it will be necessary to make use for the supply of virulent blood of those cattle only which are known to have come from areas which are absolutely free from that disease.

As regards the results which have followed inoculation with glycerinated bile followed by virulent blood my attention has been directed to a statement by Mr. Maberley in THE LANCET of Nov. 5th, 1898, and inasmuch as Lord Lister seems to have made these statements the basis of his remarks upon rinderpest I feel that in justice to myself a few definite statements which can be easily verified by anyone may serve to show the utter fallacy of Mr. Maberley's remark that "the hopes entertained at one time of the method of glycerinising bile as advocated by Dr. Edington have proved fallacious" In the Cape Colony inoculation (of one sort or another) has been practised in 57 districts. Of these inoculation by glycerinated bile followed by virulent blood has been carried out in 23 districts. In 11 other districts it has been carried out to a greater or less extent. The total number of cattle inoculated by it in the 23 districts where it only has been used amounts to 393,777. The total mortality in these districts has amounted to 32,464 animals, or 8 24 per cent. In one such district (Middelburg) the young newly-born stock on the farm of Mr. Struben became affected by rinderpest 15 months after the inoculation had been completed. Although these were running with the others of the stock not one of the latter became affected, thus showing the immunity to have been quite perfect at 15 months after the inoculation.

Grahamstown, South Africa.

PAROXYSMAL SNEEZING AND ALLIED AFFECTIONS.[1]

BY JAMES B. BALL, M.D. LOND.,

PHYSICIAN IN CHARGE OF THE THROAT DEPARTMENT, WEST LONDON HOSPITAL.

PAROXYSMAL sneezing and affections of a closely allied character are very common. The complaint varies a good deal in severity and in the character of the symptoms. Sometimes it is only a trivial ailment; at other times it gives rise to considerable inconvenience, while in certain instances it renders life miserable for a portion of the year, if not for the whole year round. The characteristic symptoms are sneezing and running from the nose. Many other symptoms are apt to be associated with these in different cases, such as stoppage of the nasal passages, smarting, burning, or itching in the nose or conjunctiva, running at the eyes, various discomforts of the throat, and, most important of all, asthmatic symptoms. In dealing with this subject I propose to keep as far as possible to the practical side of the question and to give the results of my own experience and the views founded on such experience. It is not my aim to give a *résumé* of all that has been written on the subject and I have no new theories to advance. For the purpose which I had in view I carefully looked over the notes of 112 cases which have been under my care. These notes form sufficient material for a brief sketch of the chief forms of the complaint. They supply some indications of the etiology of the disease and they show how far the various modes of treatment which were tried were successful or otherwise

The cases which we include, for want of a better name, under the term "paroxysmal sneezing" are met with under many varieties in respect of severity of symptoms, of the prominence of particular symptoms, and of the exciting causes of the paroxysm. The term "hay fever," *often* employed to denote this complaint, is, I think, best reserved for the particular variety indicated by the name, and "vaso-motor rhinitis," a name recently introduced, has the defect of committing one to pathological views which may be right or wrong, so that on the whole, I think, "paroxysmal sneezing" is the best designation. A common type of case is that of the individual who, every day or nearly every day, has an attack of sneezing and running from the nose lasting from a few moments to half an hour or more. The attacks mostly recur at about the same hour, the morning just after rising from bed being the commonest time. Such persons generally keep free from trouble till the usual time next day, though liable to occasional sneezing attacks from certain exciting causes, such as dust, changes of temperature, &c. Another type is that of the person who is subject to frequent attacks of sneezing and running from the nose at all times of the day or night from various causes or without assignable cause. Another set of people describe attacks lasting from some hours to some days, with exacerbations and remissions. Such attacks may recur every few days, once a week, or at longer intervals: "very bad colds" they usually call them, coming on suddenly and going off suddenly—"as bad as I can be one day and perfectly well the next," as one patient said. Many of the sufferers from any form of the complaint say that they are worse at certain periods of the year, but there is one well-known class of persons who suffer mainly or exclusively at a particular season—viz., for some five or six weeks in June and July—hay-fever patients, in fact. I say mainly or exclusively, for I think that it is very rarely indeed exclusively. These hay-fever patients almost always suffer from a more or less marked liability to attacks of sneezing at all times of the year, but they suffer especially at this period of the year from the disease and its accompaniments and often with an intensity and virulence hardly met with in any other class of cases.

---

[1] A paper read before [illegible] Society on Jan. 11th, 1899.

Sneezing is the prominent symptom in most cases. It is generally preceded by a tickling or irritation of the nose which, however, the sneezing fit does not always relieve, and in a general way patients do not get the satisfaction out of a sneezing attack which usually accompanies this physiological reflex in the normal condition, and in bad cases it shakes and exhausts the patients so that they perfectly dread the attacks. Some of these patients sneeze a great number of times in succession. Thus one woman who had particularly bad attacks on getting into bed at night and who counted the sneezes at my request, sneezed one night 232 times close together and 72 times after a short interval, and on another night she sneezed 294 times right off. In many cases the profuse thin sero-mucous running from the nose is the most prominent and troublesome feature of the complaint. Accompanying, as it does, the sneezing attacks it may continue after the sneezing has subsided and it may occur independently of any sneezing. The discharge may be very copious and may drip from the nose when the head is bent forward and it may be the sole symptom for which the patient seeks advice. The number of pocket-handkerchiefs used is often mentioned as a measure of the trouble. Thus I find notes of from 30 to 40 handkerchiefs a week being used in one case and 12 or 13 a day in another. The discharge is mostly periodical, occurring every day, often at the same hour, and it may be several times a day. The attack may be ushered in by frontal or supra-orbital pain, a feeling of "pins and needles" across the bridge of the nose and of irritation in the nose. Some sneezing generally marks the onset but sometimes there is little or no sneezing. Various exciting causes—dust, cold air, &c.—may produce the attack. This condition has been called "rhinorrhœa" and remarkable cases have been recorded of an almost continual flow from the nose, amounting to many pints a days, for days and weeks together. I would not say that all cases without exception of rhinorrhœa, or watery discharge from the nose, are allied to paroxysmal sneezing, but with very few exceptions they are. In some cases it is only on careful inquiry that you get any history of sneezing, the patient attributing little importance to it in comparison to the main trouble—the running from the nose. Every gradation, however, exists between one of these cases of rhinorrhœa with only a slightly marked tendency to sneeze and an ordinary case of paroxysmal sneezing.

Although sneezing and running from the nose are the most characteristic symptoms there are many other symptoms which may be present in greater or less degree. There may be a feeling of intense tickling, irritation, or itching in the nose, sometimes confined to one passage. Sneezing may not relieve it and sometimes there is a constant desire to sneeze without the ability to do so. Stoppage of the nose is common. Most patients describe a stoppage at the onset which is relieved by sneezing and running. Many patients have a chronic obstruction of one or both passages more or less marked, but this is a separate matter from the intermittent stoppage of which I am speaking. The ocular symptoms are extremely marked in some cases. The eyes stream with water, one eye sometimes more than the other, and there may be intense irritation or itching of the eyes and a constant desire to rub them. The eyelids may even become puffy and œdematous. Itching and irritation of the inner canthus of one or both eyes is the earliest sign of an approaching attack in some persons. Headache is a common symptom. The pain is mostly referred to the frontal or supra-orbital region and is dull and heavy or neuralgic in character. Some describe the pain as much relieved when running at the nose begins. Irritation and itching of the soft palate and fauces are complained of in many cases. There is one very important group of symptoms from which these patients frequently suffer—viz., oppression or tightness of the chest, wheezing, paroxysmal cough, or definite asthmatic attacks. Of my patients I find that 56, or exactly half, suffered more or less from these asthmatic symptoms. In the great majority of them the paroxysmal sneezing existed for months or years before the asthmatic symptoms appeared. In a few the two sets of symptoms seemed to develop simultaneously. In three of my cases I noted that the asthmatic symptoms existed for some time before the sneezing. Many patients described each attack as being habitually preceded by sneezing. This association of paroxysmal sneezing and asthma has long been recognised. The patients whose cases form the subject matter of this paper were, of course, all more or less pronounced sneezers, but if you were to inquire into a series of cases of pronounced asthma you would get the same evidence of the striking association of this disease with paroxysmal sneezing. It is only on careful inquiry that you will elicit the fact, as asthmatic patients attach little importance to the sneezing symptoms, but in almost all "asthmatics" you will get a present or past history of liability to attacks of sneezing.

Many subjects of paroxysmal sneezing describe the attacks as coming on without any cause that they can assign. Women sometimes find that their attacks are worse at the menstrual periods. In a great many cases the attacks recur at particular periods of the day. The morning is the usual time and most patients have an attack on getting up in the morning. Some begin to sneeze immediately they awake in the morning. Attacks may recur regularly at a particular period of the forenoon or the afternoon. Some always have an attack on getting into bed at night. One of my patients woke up regularly at 4 A.M. with intense irritation in the nose followed by sneezing. One patient always sneezed after meals. Some patients were always worse in London and some were worse in the country; some were worse in winter and some were worse in summer. Most patients were affected by going into bright sunshine. Dust is the most frequently mentioned cause: all kinds of dust, in- and out-door, some being affected more by one than the other. Change of temperature is often assigned as a cause, such as going into hot rooms or out into the cold. Hay, of course, is an exciting cause in many. But the idiosyncrasies of patients in respect of the exciting causes are, as we know, extraordinarily varied. In my notes I find specified such causes as tobacco smoke, the atmosphere of the Underground Railway, roses, sweet peas, lilies, any kind of flowers, bird-seed, linseed cake, furs and skins of animals, the proximity of a cat (especially a Persian), a cold bath, a hot bath, using soap for washing the face, brushing the hair, drinking cold water, the act of talking and singing, violent exercise, &c.; but the possible exciting causes are innumerable and the foregoing list could be added to indefinitely from the experience of patients of this class.

I may now pass from the exciting causes of the paroxysm to the etiological conditions underlying this affection. Looking through my own cases I find that there are 59 males and 53 females, so that the sexes are pretty evenly divided. The cases were of all ages, from three years up to 68 years of age, the majority being between 20 and 40 years. It is of more interest, however, to see at what age the complaint first showed itself, and in 94 cases I have a note on this point. I find that 16 began before 10 years of age, some of them in infancy. 27 cases began between 10 and 20 years of age, 21 between 20 and 30 years, 18 between 30 and 40 years, and only 12 after 40 years of age. 51 cases out of 94, or 54 per cent., commenced before 25 years of age. It is clear that the disease usually develops in the earlier period of life, but it may begin at any age, occasionally at a very advanced age. That the disease is hereditary and that it runs in certain families is very clear. In many of my cases there is a history of similar troubles in parents and grand-parents and various collateral relations. I have already alluded to the close connexion between paroxysmal sneezing and asthma and this is well illustrated by the history of asthma in members of the same family. In 33 per cent. of the cases I was able to get a history of either paroxysmal sneezing or asthma, or both, in one or more members of the family of the patient.

I now come to an important matter—viz., the condition of the nasal passages in these cases. In a certain number of my cases excessive sensitiveness of the interior of the nose when touched with a probe either at certain points or throughout was noted. In many cases, I think in the majority, no such hyperæsthesia was present. Apart from this I find that in the 112 cases there existed some pathological condition of the passages in 104, or nearly 93 per cent. This is a large proportion and I might admit that possibly it is a larger proportion than would be found in the same number of cases taken at random, because I think it possible that I might get a preponderance of cases in which certain symptoms, such as chronic nasal obstruction, were present or in which there was known to be some nasal disease or abnormality. I doubt, however, if this makes a very great difference, as certainly the vast majority came simply on account of the sneezing and running from the nose. At any rate, the proportion in these cases was as I have given it. The following are the various abnormalities noted, and I should like to say that under the head of "septal deflections, crests, and spurs" I do not include every slight deviation or inequality of the septum, for these are extremely common in all persons, but only such as cause obstruction to respiration or such as bring some part of the septum into close proximity or firm apposition with the turbinated bodies. In 40 cases marked deflections, crests, or spurs were the only pathological conditions noted. In 33 cases hypertrophic rhinitis was the chief feature noted, in 12 of which septal deformity coexisted. In 20 cases mucous polypi were present, combined with septal deformity or hypertrophic rhinitis in several cases. Enlargement of the middle turbinal was the chief condition noted in five cases and adenoid vegetations in five cases. In one case there was a remarkable atrophic condition of the mucous membrane and turbinals, not however of the nature of fœtid atrophic rhinitis. There was a profuse, thin, watery discharge in this case and complete anosmia. It will thus be seen that septal deflections, crests, and spurs were the most frequent abnormality, being present not, as I have already said, in a slight or trivial degree, but in a marked degree in 40 cases as well as in combination with hypertrophic rhinitis, mucous polypi, or adenoids in at least 20 other cases. In 22 cases a crest or a spur on the septum was noted as being jammed firmly against the inferior turbinated body. In four of these cases the irritation was felt almost exclusively on the affected side and the running was chiefly from that nostril.

Although there can be no doubt as to the frequency of pathological conditions in the nose in cases of paroxysmal sneezing the question arises whether they are in any degree the cause of the symptoms and how these pathological conditions can give rise to such symptoms. It is well known that such conditions as septal deflections, hypertrophic rhinitis, mucous polypi, &c., exist very frequently without any paroxysmal sneezing and, in fact, it is only in exceptional cases that such symptoms arise. It must be admitted, also, that hypertrophic rhinitis may well develop during the course of the complaint as a result of the frequent congestive swelling which takes place, though, of course, in many of my cases where the symptoms were comparatively recent and the hypertrophy well marked I could exclude this view. I think, too, that in some cases of mucous polypi it was probable that paroxysmal sneezing existed before the development of the polypi and it seems that the complaint favours the growth of polypi. This, however, is the exception. There can, in fact, be no doubt that various pathological conditions are present so frequently in this complaint that in some way or other they unquestionably form an important etiological factor in a large proportion of cases, but, of course, only one factor, since the complaint may arise independently of them, and all these conditions frequently exist without any symptoms of the complaint.

The question then arises, What other factors enter into the causation? The most constant phenomena of the complaint are sneezing and certain vaso-motor and secretory disturbances in the nasal mucous membrane as well as in the conjunctiva and lacrymal apparatus. All these phenomena are capable of being reflexly excited. Sneezing is a familiar nasal reflex. The increased flow in coryzal conditions is partly due to increased glandular secretion and partly to serous transudation from the nasal mucous membrane. It is in part the result of vaso-motor disturbances but not wholly so. The vaso-motor and secretory functions are under the control of the nervous system and are reflexly excited by familiar causes. In the complaint which we are considering all these reflexes are excited by causes which would not act on the normal individual. We may therefore suppose that in these cases there is an undue excitability of certain nerve-centres, owing to which they are called into action by influences which would not otherwise affect them. This may or may not be a part of a general neurasthenia inherited or acquired; in some cases it certainly is, for, as we know, a fair number of these patients are what we term neurotic, though by no means all. It also seems probable that prolonged irritation arising from certain abnormal conditions in the nose may set up this morbid excitability in the nerve-centres connected with the sensory nerves of this region, though here also we are compelled to assume a predisposition in the individual, since intra-nasal disease as a rule does not set up paroxysmal sneezing. That there is this predisposition in many cases is evidenced by the frequency with which we get a history of similar complaints in many members of the same family. This is all I shall say by way of suggestion in relation to this question, merely adding that a good many of my patients date the onset of their symptoms to an attack of influenza which is well known to be capable of disturbing the nervous system in various ways.

I have already alluded to the frequency with which asthmatic symptoms occur in subjects of paroxysmal sneezing and of the close relationship between the two complaints. On this point I may remark that asthma is admitted to be sometimes excited reflexly by nasal disease or irritation. It has been shown by experiments on animals that contraction of the bronchial muscles can be set up by irritating the nasal mucous membrane (François-Franck, Lazarus). In certain cases of asthma it is possible to cause a temporary abatement of the symptoms by the application of cocaine to the nasal passages. This is a fact which I have repeatedly verified for myself. It is probable, therefore, that in many cases the asthma associated with paroxysmal sneezing is of nasal origin and is reflexly excited by nasal irritation, at any rate in the first instance, for when once established there is reason to believe that asthma may be excited by various causes other than the original cause. In some cases the asthma is not a reflex result of nasal irritation but merely a coincident disturbance in the lower part of the naso-bronchial tract. It is probable that in some cases of asthma associated with paroxysmal sneezing the irritants in the air which set up the paroxysmal sneezing act directly on the lining of the bronchial tubes and so excite asthmatic symptoms. I have already alluded to paroxysmal cough as a not uncommon symptom in subjects of paroxysmal sneezing. Cough is another undoubted nasal reflex; it is well known that paroxysmal cough is often a precursor of asthma and it may replace an asthmatic attack.

Before speaking of treatment it will be well to consider for a moment the course of the complaint in its various forms if left to itself. The course of the cases is extremely variable and uncertain and this must be borne in mind in estimating the value of treatment in paroxysmal sneezing. Some cases continue for years or throughout life without any marked change. Cases may get well or undergo marked increase at any period of life. An attack of influenza sometimes causes marked exacerbation of the symptoms. Patients who get well may relapse again after a variable period. There is in most cases apt to be an abatement of the symptoms after middle life, but there is no uniformity in this respect. Some suffer right on into old age. Changes take place, too, with regard to the influence of exciting causes. Certain patients, for instance, state that at one time hay used to affect them severely but that latterly they are no worse in the hay season than at other times. A change in the character of the symptoms is not infrequently noticed, the sneezing symptoms subsiding and an aggravated condition of rhinorrhœa becoming established. Asthmatic symptoms may set in at any time in [illegible] course of the complaint. They usually [illegible] early period [illegible] within the first two [illegible] gone on several years without any symptoms, such as tightness or oppression of the chest or wheezing or paroxysmal cough, are likely to escape, but there is no certainty. Once asthma has definitely appeared it may outlast the coryzal symptoms, the latter disappearing completely while the asthma becomes confirmed. Sometimes the asthmatic and the sneezing symptoms alternate in a curious way.

I must now pass to the treatment of paroxysmal sneezing. I have carefully studied the notes of my cases on this point and I shall endeavour to state the conclusions which I believe may fairly be drawn from a study of them. Only a certain proportion of my cases were fully available for this purpose. Some cases I only saw once and treatment was either not begun or not pursued; others were kept under observation for a short time, too short to judge of the final result but sufficiently long to furnish indications as to the immediate effect of treatment and the influence of palliatives. Some of the cases are too recent to speak of them as "cured" or "permanently relieved," as until at least a year has passed from the cessation of treatment I do not think we should begin to use these terms.

My remarks for the present apply only to the coryzal symptoms; at the end I shall say something of the asthmatic symptoms. The first and most important fact which a study of my cases proves is that a large number of these cases can be cured or so much relieved as to be practically cured, and the second is that this can only be attained by local treatment, by remedying the various morbid conditions which I have already enumerated as being present in so large a proportion of the cases. But for this end the local treatment must be thorough and effective. Now I do not wish it to be understood that every patient suffering from paroxysmal sneezing in whom intra-nasal abnormalities exist should be treated operatively. It depends on the severity of the symptoms and to some extent on the operation required. Some of these patients suffer comparatively little trouble and do not need to be subjected to operation; but if the symptoms are severe, or if for any reason whatever we desire to ensure something approaching a permanent cure, a thorough radical treatment of such intra-nasal morbid conditions as are present is essential. Now we learn as much from studying our failures as we do from studying our successful cases. I have had plenty of failures, but a close scrutiny of them convinces me that the cause of the failure was almost always due to the inadequacy of the treatment. This was not, of course, always my fault. A patient will submit to a few applications of the galvano-cautery when the use of the saw to remove a spur or crest may be objected to, or you may be permitted to remove a few mucous polypi with the snare when the proposal to operate on a coexisting deflected septum will not be accepted, and so on.

There are some cases, the number of which is, however, limited, in which treatment by the galvano-cautery (or escharotics such as chromic acid) will be sufficient. I can only find two cases which could be said to be in any sense cured by this treatment. There was more or less relief noted in 10 cases. Against these I find 12 cases in which no improvement was obtained. Some of them were afterwards improved or cured by other measures. The galvano-cautery is especially indicated for cases where the sole condition is a chronic turgescence or very moderate hypertrophy of the inferior turbinal and where by its use we may be able to prevent contact between these bodies and the septum even when these bodies become congested. It is also useful for cauterising excessively sensitive spots in the mucous membrane, if any such are present. When spurs or crests project from the septum against the turbinals they must be sawn off. Deflections of the septum of all kinds must be so treated that the passage shall be left free for respiration and all possible contact with the turbinals, especially the inferior, shall be prevented. For this purpose the turbinals themselves may have to be partly or wholly removed. When the inferior turbinals are hypertrophied the snare and punch forceps must supplement or replace the galvano-cautery and in some cases complete removal of one or both inferior turbinals is the only plan to adopt, and no theoretical considerations must be allowed to interfere with this procedure if it is desired to relieve the patient. I am convinced of this. If mucous polypi are present they should, of course, be removed and more or less alleviation of the symptoms may be expected, but the patient will not be cured, and perhaps not much relieved, unless other co-existing conditions, such as deformities of the septum or hypertrophied turbinals, are treated. I have collected 31 cases in which I was able to carry out treatment on the lines now indicated. Among these there appeared to be only one case in which there was no relief of the symptoms. 25 cases were completely cured or so much relieved that their symptoms gave them no particular trouble. Some have now continued so for several years. Four were relieved but still continued to suffer in a minor degree from their former trouble. One, though considerably relieved for some weeks after the operation, was lost sight of and cannot therefore be counted. I have a few other cases which promise equally well with the foregoing, but as a year has not elapsed I prefer not to include them.

In contrast with these cases are those in which for various reasons only medicinal treatment was employed. No one admits more freely than I do the presence of a neurasthenic element in many of these cases. I have prescribed all the usual nervine and other tonics which one gives in such cases. Many of the cases operated upon have had a trial of drugs and local applications for a time. I have frequently seen considerable relief as the result of drugs, but anything which could be called a cure—any case in which drugs could be left off and permanent freedom from symptoms be anticipated—I unfortunately have not seen. Still, a great deal of relief can be got from the use of general and local remedies, and for various reasons it is the only form of treatment one can employ in many cases, and they may be usefully employed in conjunction with other modes of treatment. Few complaints have had more remedies vaunted for their relief, and probably most of them are occasionally useful. I need not enumerate them, nor need I refer to the treatment of any general neurasthenic condition which may be present or to such obvious measures as protecting the patient from the known exciting causes by change of residence, &c. I shall content myself with referring to a few remedies which I most frequently employ.

The internal remedies which I believe to be most often useful are quinine, belladonna, arsenic, and iodide of potassium, but I confess that I know of no reliable indications for giving preference to one or other of these drugs in particular cases. I give quinine in moderate doses of from one to two grains three times a day and it certainly sometimes relieves, but more usually I combine it with iodide of potassium or arsenic. Belladonna is often useful and occasionally gives striking results. I generally prescribe the extract in a dose of from one-twelfth to a quarter of a grain two or three times a day. Arsenic is, I think, useful in many cases, though less so than belladonna. A prescription which I employ very often is a pill containing one grain of sulphate of quinine, one-sixteenth of a grain of iodide of arsenic, and one-twelfth of a grain of extract of belladonna, to be taken three times a day, the arsenic and belladonna being increased according to tolerance. I have seen this pill taken through the hay season by patients with marked alleviation of the usual symptoms. Iodide of potassium is especially useful in cases associated with asthmatic symptoms and I always lead off with it in such cases in full doses of, say, 10 grains three times a day; I sometimes combine with it arsenic and quinine.

The local remedies which I have most frequently used are cocaine and menthol. Cocaine, as is well known, if applied at the onset of a paroxysm generally gives remarkable relief, lasting an hour or two. A 4 per cent. solution is sufficient and may be applied with a spray apparatus or on a pledget of wool soaked in the solution. A solution of cocaine in hazeline is sometimes more efficacious. Some caution is necessary in prescribing cocaine as toxic effects are sometimes caused and the prolonged use of cocaine seems to set up a certain kind of nervous irritability. Bearing this in mind, however, and using some judgment we need not discard this remedy which acts as a valuable palliative in severe cases. Menthol is a useful application in many cases and has not the disadvantages just mentioned with regard to cocaine. It dissolves well in a liquid paraffin preparation such as paroleine. A 1 per cent. solution is generally strong enough. It may be used as a spray or may be applied directly on cotton-wool. Menthol-camphor is also useful in 1 or 2 per cent. solution in paroleine. While cocaine should only be used to check severe paroxysms menthol and menthol-camphor may with advantage be used several times a day both during and between the paroxysms.

In conclusion I must say a few words with regard to the effect of intra-nasal treatment upon asthmatic symptoms when these are associated with paroxysmal sneezing. In the majority of cases the asthmatic symptoms were relieved more or less by the line of treatment which relieved the nasal symptoms. In the 31 cases already referred to about half were subject to asthmatic symptoms, either some feeling of tightness or oppression of the chest, some wheezing at times, or definite attacks of asthma. I can only find one who though much relieved of his nasal symptoms got no relief from his asthma which indeed steadily got worse. On the other hand, some though relieved were by no means relieved to the same extent as in respect of the nasal symptoms. I suspect, if we could only know it, that we relieve the asthmatic symptoms in so far as these depend upon reflex excitation from the nose, but it is impossible to say how far this is so in any particular case. As I have already said, it may be so in the early period of the case and not so later. The general conclusion which I have formed on this matter is that in children and young subjects affected with paroxysmal sneezing there is a much better chance of relieving or curing the associated asthmatic symptoms than in older subjects; that the shorter the period during which the asthmatic symptoms have been present and the less pronounced they are the more likely we are to relieve or cure them by the same treatment which relieves or cures the nasal symptoms. Still our prognosis with regard to asthma in these cases should always be guarded.

Upper Wimpole-street, W.

PARALDEHYDE IN ASTHMA.

BY ALEXANDER MACGREGOR, M.D. ABERD.,
M.R.C.P. LOND.,
PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST AND PHYSICIAN TO THE WESTMINSTER GENERAL DISPENSARY.

As far as I have been able to find out, Dr. Mackie[1] of Elgin was the first to suggest the use of, and to use, paraldehyde for the relief of asthma. "The fact that paraldehyde is a sedative largely eliminated by the breath" led him to try its effect in the spasm of idiopathic asthma. He administered it in a number of cases with uniformly successful results and found that it speedily relieved the spasm and induced sleep. My attention was drawn anew to this a few months ago and since then I have given the drug in a fairly large number of cases of idiopathic asthma and other forms of spasmodic dyspnœa and my experience confirms that of Dr. Mackie. No drug in my hands has given such satisfactory results. In the treatment of hospital out-patients suffering from asthma morphine hypodermically is out of the question and it is not usually advisable to prescribe chloral in such cases. Paraldehyde is absolutely safe. It not only relieves the spasm but it induces tranquil refreshing sleep without any objectionable after-effects. Besides, no evil results follow a prolonged use of paraldehyde; it does not give rise to a habit, and on this account it is a much more desirable drug than morphine or chloral. That it has hitherto not been much used in the treatment of asthma one may safely conclude from the fact that neither in Allbutt's "System of Medicine" nor in "Twentieth Century Practice of Medicine" is it mentioned among the drugs given as useful in the treatment of the disease. I venture therefore to think that the following short notes of a few of the cases in which I have used it may prove interesting and worth recording.

CASE 1.—The patient was a woman, aged 24 years, who had suffered from asthma for four years. The nightly attacks of dyspnœa had always been very severe and protracted. Chloral gave no relief. She had derived most benefit from a mixture containing iodide of potassium, tincture of lobelia, and solution of hydrochlorate of morphia; but this combination and many other remedies gave relief only for a short time and her condition became serious. She was losing flesh, cyanosis was constant, and she was gradually growing weaker. On Sept. 30th, 1898, she was ordered half a drachm of paraldehyde every night at bedtime. When seen a week afterwards she said that since taking the paraldehyde her nights had been very good, that she had had only one attack, and it was a very short one. The dose was doubled and then the attacks ceased. On Jan. 6th, 1899, the note in the case-book says: "She continued to take the paraldehyde up to Nov. 18th and has taken none since. Her nights are invariably good. Now and then she has a slight wheezing attack which lasts only for a few minutes. She has put on flesh and her colour is quite rosy."

CASE 2.—The patient was a woman, aged 37 years, who had been ill for three months; there was a family history of phthisis. At first the attacks of asthmatic dyspnœa came on chiefly after meals and for a time they were relieved by iodide of potassium and tincture of lobelia. In this case and in several others an occasional dose of a carminative mixture seemed greatly to increase the effect of the other remedies. Very soon the latter had little or no effect, she became much worse and the dyspnœa and laboured breathing prevented sleep. Half a drachm of paraldehyde, repeated in an hour, gave tranquil, refreshing sleep. She continued to take paraldehyde for several weeks and the last note of her case says: "Her nights are good and she reports herself to be ever so much better."

CASE 3.—The patient was a woman, aged 36 years, who had suffered from bronchitis off and on for nearly three years. An uncle was asthmatic. She had had a severe attack of influenza in January, 1898. She was first seen on Nov. 15th and she stated that for three months she had suffered from attacks of dyspnœa coming on suddenly during the night, usually about 1 A.M.; she awoke struggling for breath, the attack, with much wheezing and laboured breathing, lasting often for 12 hours or longer. She had had a very bad attack the night before her visit and she was still decidedly cyanotic, but on examination no adventitious sounds were heard in the lungs and the heart was normal. A mixture containing iodide of potassium was ordered to be taken during the day and paraldehyde at bedtime. When next seen, on Nov. 22nd, her report was: "I feel much better, I sleep all night and wake feeling so refreshed." On Nov. 29th the report states that a severe attack occurred on the night of the 26th, the usual dose of paraldehyde induced sleep only for a very short time, and although sleep for the rest of the night followed a second dose the asthma recurred when she awoke and continued till the following evening. She was last seen on Jan. 3rd, and she then stated that she was quite well, that she had not taken paraldehyde for a week, and that she now slept well all night. There had not been an attack since the one mentioned above.

CASE 4.—The patient was a man, aged 44 years, who had suffered from asthma for nearly two years before coming under observation. At first the spasmodic attacks occurred about 2 A.M., but lately they had come on frequently during the day. The lungs were emphysematous and he also had got a mitral systolic bruit. At first he was given paraldehyde and nothing else. More sleep was the result but it was somewhat restless, and he often awoke wheezing, coughing, and retching. He was then ordered a mixture containing iodide of potassium and tincture of lobelia to be taken during the day and the paraldehyde at bedtime. Under this he improved immensely, and a note made after adopting this treatment says that "the nights are good and breathing easy during the day. Has been at work for a week."

CASE 5.—The patient was a woman who had suffered from asthma for four years. Her father had been asthmatic for 20 years and six of his eight children suffered from the same disease. The nocturnal paroxysms were very severe and in addition to the usual characteristic symptoms there was a patch of catarrhal pneumonia at the base of the left lung. She was ordered an expectorant mixture with iodide of potassium during the day and paraldehyde at night. On each of the first two nights almost immediately after taking the paraldeyde she fainted but slept quietly all night. After that the drug did not cause even a feeling of faintness but gave the patient quiet nights and there was no recurrence of the asthmatic attacks.

CASE 6.—The patient was a woman, aged 47 years, stout, flabby, and very neurotic; she was first seen on Nov. 5th, 1897, when she stated that she had suffered, off and on, for several years and had been gradually getting much worse. Her father was asthmatic and so was a sister who, she said, died in an attack for which she was given morphia hypodermically. At her first visit this patient was cyanotic, her breathing was noisy and laboured, and the usual pulmonary signs were present in a marked degree. For a time she was much relieved by iodide of potassium and tincture of lobelia. After an absence of several months she returned for advice on Sept. 30th, 1898. Sl [illegible] then h [illegible] least one severe attack of asthma each [illegible] fits of sneezing. She was [illegible] hyde each night. For three nights she slept well, but after that the drug caused excitement. The dose was doubled, she then slept very well and the breathing was much improved. The sneezing fits ceased after she began to take the paraldehyde.

---

[1] Brit. Med. Jour., vol. i. p. 65, 1893.

Case 7.—The patient was a man, aged 36 years, who had been ill for 11 months. Asthmatic symptoms came on after an attack of influenza. He complained of shortness of breath, cough, loss of flesh, and night sweats. He said that he "could get no sleep because of the cough and the struggle for breath." He was given iodide of potassium during the day and a drachm of paraldehyde at bedtime. A week afterwards he reported himself to be much better and said that he now slept comfortably all night. The note in the case-book a month after he began the treatment says, "He sleeps well and is putting on flesh; he has gained 6 lb."

Case 8.—The patient was a man aged 34 years who had been ill for two years. He complained of a very bad cough, profuse expectoration, and loss of flesh. He also stated that frequently during the night he had to spring out of bed because of a sudden sense of suffocation which ended in a severe and prolonged fit of coughing. He was ordered the same treatment as in the last case but only four doses of paraldehyde were given. When seen a week afterwards he reported that during the first two nights his sleep had been unbroken, that the next two nights it had been very good, and that although without paraldehyde for the three following nights he had had no attack and was able to lie quietly in bed all night.

Case 9.—The patient was a woman, aged 30 years. She was neurotic and had been ill for three months. She was first seen on Dec. 6th, 1898. An aunt had suffered from asthma for 18 years. This patient complained of a painful sense of tightness in the chest, shortness of breath, and a troublesome cough, and she was subject to severe attacks of spasmodic dyspnœa during the night. The same treatment was ordered in this case. Immediately after taking the first dose of paraldehyde she fainted and had to be lifted into bed. She said that "the medicine was so strong that it took her breath away," but the result was that she slept all night. She did not continue the paraldehyde, but with iodide of potassium, &c., she improved and on Jan. 3rd, 1899, the report said that she was ever so much better and sleeping well.

Case 10.—The patient was a woman, aged 34 years, who had suffered from asthma more or less for 14 years. She had had three attacks of rheumatic fever. The heart was normal. At her first visit she was very cyanotic, the shortness of breath was distressing, and the breathing was noisy and laboured. The symptoms were greatly aggravated at night and made sleep practically impossible. An expectorant mixture during the day and paraldehyde at night gave marked relief; she was able to sleep comfortably, and the breathing soon became easier. She continued to take paraldehyde for some weeks and always with benefit; the cough disappeared, and after a time she was able to dispense with both the expectorant and the paraldehyde.

Case 11.—The patient was a woman, aged 43 years. She had suffered from asthma and bronchitis for five years. In her case the symptoms were severe, the cough was troublesome, and she got very little sleep because of the attacks of spasmodic dyspnœa which were frequent and painfully distressing. In addition to an expectorant mixture she was given a drachm of paraldehyde at bedtime. The latter medicine, to use her own words, gave her beautiful nights and she always felt so refreshed after the sleep.

The mere obtaining of sleep is of great importance for the asthmatic patient, the strength is saved and what is lost during the day may be more or less regained. The prevention of the spasm is even a greater boon, seeing that each attack increases and prolongs the accompanying bronchitis. Iodide of potassium and tincture of lobelia as a rule do much to relieve the bronchitis and to lessen the spasm, but their effect is immensely increased by securing sleep and the prevention of the nocturnal spasms by means of paraldehyde. The drug occasionally causes sickness and for this reason it proved of no use in a severe case of long standing bronchitis and emphysema. Its disagreeable pungent taste makes it objectionable to children and nervous patients, but it is well disguised in cinnamon water and tincture of orange-peel. It acts as a rule so rapidly that the dose ought to be taken after the patient has gone to bed. In the case of more than one of my patients it seemed to act immediately and for this reason one nervous man suffering from simple insomnia refused to continue taking it. In adults I find it best to begin with a dose of 60 minims, and as Dr. John Gordon[2] pointed out, as a result of his experimental use of the drug, the same dose has equally good hypnotic effect when it has been taken for months. Although Dr. Gordon does not mention asthma among the diseases in which he found paraldehyde useful as a hypnotic one of the results of his investigations might suggest its use in this disease. He found that it produced tranquil sleep with diminished respirations and in his paper on the subject he says, "This slowing of the respirations in many pulmonary diseases is of distinct advantage." He further says, "It is possible that, since a large amount of the drug is excreted by the lungs, its vapour may exercise a narcotic influence on the terminations of the sensory nerves of the lung tissue while it is being expired." One can, therefore, easily understand how, by its double action of inducing sleep and preventing pulmonary spasm paraldehyde has such a powerful effect for good in asthma.

ON THE TREATMENT OF "UNAVOIDABLE HÆMORRHAGE" BY REMOVAL OF THE UTERUS.

By LAWSON TAIT, F.R.C.S. Eng. & Edin.,
CONSULTING SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN, AND TO THE LIVERPOOL, NOTTINGHAM, AND SOUTHAMPTON HOSPITALS FOR WOMEN.

I have spent much of my leisure during the last few weeks in looking up the authorities on "placenta prævia" for some assured statement concerning its mortality. There is nothing more definite than is to be found in Simpson: "All obstetric authors seem to agree on this point, *that there* is no one complication in midwifery attended with more anxiety to the practitioner and few, if any, with more real danger to the patient than cases of unavoidable hæmorrhage from presentation of the placenta." He proceeds to give figures which go to show that the fatality is close on 40 per cent., but I gather from the smothered confessions of other writers and the open admission of my friends who have had large obstetric experience that it really is much higher; and in spite of the sound principles laid down for its treatment and the improvements therein made by Simpson himself it is probable that more than half the cases die. I have all my life avoided in every possible way contact with obstetric practice, and for 30 years have had no personal association with it save in occasional consultations. Amongst these have to be included 13 (now 14) cases of unavoidable hæmorrhage and of this the mothers have died in seven cases and, I think, only three of the children were born alive. It will therefore not be a matter of surprise if I say that I entirely agree with the sentence which I have quoted from Simpson's "Obstetric Works." I feel pretty sure that the full mortality of the condition is not yet known, so many patients die from the secondary complications due to the damage of the misplaced placental sinuses; and as these cases are generally not fatal till many days *after delivery they* are not returned as cases of "placenta prævia" but as peritonitis, &c. I gather from conversation that only immediate deaths are as a rule entered under the real and primary cause. This is of itself a point of interest about the condition, but not one which concerns me much, though evidently the higher the total mortality is found to be, primary and secondary, the stronger will be my subsequent argument from this point of view.

Another aspect from which "unavoidable hæmorrhage" is extremely interesting is that it is one of the few points in the practice of surgery where our conduct may be influenced by ecclesiastical authority. The Church of Rome rules that in such a case the living birth of the child is all important and when the interests of mother and child conflict those of the former must yield. In one case to which I was called by the late Dr. Wynne Thomas this decision, arrived at by the mother and the father of the child, as advised by their spiritual directors, seemed to us to cost the mother her life though it did save the child. Under such circumstances that part of the treatment directed against the immediate risk from hæmorrhage has its influence for good directly contravened and probably entirely annulled by the causes introduced and the risks produced of secondary mortality. All these conditions existed in a case to which I was called on Dec 21st, 1898, by Dr Herbert Simpson of Rugby. The patient was young and slightly built and had as bad a history of hæmorrhage as a woman well could have She had always had "something wrong" inside and had been a regular consumer of ergot for years She had been twice curetted and cauterised She had nearly lost her life from post partum hæmorrhage in her second confinement, had had several miscarriages with severe losses, and I found her in her fourth confinement at the full time with the cervix closed and rigid, the liquor amnii drained off, the uterus firmly contracted over the child, and yet she had been bleeding with alarming profusion for five hours, in spite of many other and orthodox points of treatment which Dr Simpson had employed The child was easily ascertained to be alive and the considerations of its interest as superior to that of the mother were not pressed by anyone But I confess that the recollection of previous experiences made me hesitate to do what was clearly necessary, forcibly dilate the cervix and extract the placenta, whether I followed that by version or not, whether or not I left the after labour to nature and the child to its fate An alternative occurred to me to which I was prompted by the splendid success which has followed it in my hand and in those of others under different yet very analogous circumstances—removal of the uterus It had many arguments in its favour, it would save the child, it probably would save the mother, and it would relieve her of the condition of perpetual misery and risk in which she had been living for years and would therefore assist her in properly rearing the children she had, rather than tend to procreate others to whom she certainly showed no likelihood of ever being able to give proper care There were no arguments against except the familiar one of "mutilation" As I have already characterised that as the argument of the brothel keeper rather than one for the consideration of the physician I attach little importance to it Putting myself in the place of the patient's husband, so far as I could, I felt that the Church of Rome had some reason for its decision, though more as a matter of right than of salvation—that any proceeding which would diminish the mother's risk from 50 per cent. or 40 per cent, or even 20 per cent to four or five per cent must be selected Finally, the argument would have been overwhelming with me as a husband that my wife would have health and comfort for her after life, instead of misery and risk, irrespectively of sterility or mutilation or anything else I therefore proposed hysterectomy, and after full discussion it was accepted by Dr Simpson, by the husband, and by the patient I performed it with the aid of the elastic ligature[1] by that known in America as the "Tait Porro" operation The patient made a straightforward recovery, interrupted only by occasional rectal distension A fine female child was born alive and lived for a month, succumbing, unfortunately, a month after birth when the cold weather distributed bronchitis

This case forms, so far as I know, a new departure Whether it will receive a universal commendation is not the least a matter of doubt The "mutilationists" will *raise* their voices against my proposal, but there are others who will follow my example and to those who *do this* will surely come the comfort that they will diminish "the anxiety to the practitioner and the real danger to the patient" of the obstetric difficulty which Simpson so graphically tells us has more of both than any other

NOTES ON THE PRESENCE OF TH BACILLUS COLI AND OTHER ORGANISMS IN THE TISSUES AFTER DEATH.

BY J O SYMES, M D, D P H LOND,
BACTERIOLOGIST TO THE BRISTOL ROYAL INFIRMARY

THE presence of micro organisms in the viscera after deat apart altogether from the putrefactive varieties, which not, as a rule, appear for several days, is a very commc occurrence The true significance of their presence is no however, clear, nor is it definitely known whether the appearance is a post-mortem or an ante mortem phenomeno Most observers, however, regard the invasion as taking plac during the last hours of life and this theory is supported l the work of Beco[1] who, examining bodies from one quarter t three quarters of an hour after death, found the bacillus co in the deep organs in nearly 50 per cent of the cases Wl in some cases the organs should be invaded by micro organisms whilst in others almost exactly similar the should escape is not clear, nor is it known wh certain organs should be attacked and others sparec The invasion of the deep organs by the bacillus coli and i escape from its natural habitat, the intestines, which wa formerly regarded as consequent upon some intestinal lesior has more recently been attributed to the spread of th bacilli through the biliary channels, it being generall accepted that they are not able to pass through the health wall of the gut The question of the method of thei escape and multiplication is one of some importance a bearing upon these cases of suppuration in which durin life the bacillus coli is the only organism to be foun and also in relation to the inquiries, Is infection by th bacillus coli a common complication in certain diseases and Is it capable of giving rise to symptoms or hastenin death?

During six months I have made systematic bacterio logical examinations of the organs in the necropsie at the Bristol Royal Infirmary with a view to elucidatin some of these points The appended tables are compile from notes on the first 50 cases Of these 50 cultures 1 were sterile, the bacillus coli alone or associated with othe organisms was found in 20, whilst 13 showed other varieti of bacilli or cocci

TABLE 1—*Cases in which no Micro organisms were found*

Disease	Hours after death	Organs examined
Chronic alcoholic syncope	21	Spleen and kidney
Accident, ruptured bladder	21	Spleen
Stricture of the urethra hydronephrosis	12	Kidney and spleen.
Enteric fever	?	Spleen
Cerebral tumour	24	Kidney
Chronic endocarditis	18	Kidney
Bronchitis	9	Spleen and kidney.
General tuberculosis	32	Brain and spleen.
Carcinoma of the bladder	20	Liver

General tuberculosis	20	Spleen.
Urethral fever stricture cystitis, &c.	19	Spleen.
Phthisis	18	Heart and kidney

[1] Annales de l Institut Pasteur, 1895.

The average time after death at which the examinations were made was 20 hours, whilst in the remaining 33 cases the average was 24 hours. It is possible that the difference in time may to some small extent have been a factor in determining the sterility of some of the cultures, for after death such organisms as may be in the tissues multiply rapidly, so that the longer the time that has elapsed the greater is the chance of inoculating the culture medium. In 10 cases only one of the viscera was examined. This again would lessen the chance of detection and it is possible that in the cases with intestinal lesion (enteric fever, intestinal obstruction, and septic peritonitis) failure may be attributed to one or both of these causes. After making such allowances, however, the fact is established that under ordinary conditions of temperature and surroundings in a considerable percentage of cases the tissues may remain free from bacterial invasion for a period of from 24 to 36 hours after death.

The bacillus coli was found in 40 per cent. of the cases, as is shown in Table II. From the rapid growth in gelatin, formation of gas in glucose gelatin, from the power of coagulating milk and giving the indol reaction, the bacilli were shown to belong to the Escherich group. Alone no one of these tests is to be relied upon, the indol test being particularly fallacious. A valuable means of distinguishing between bacteria of the Escherich and Gärtner groups is the difference in their reaction to typhoid serum, the former never giving a positive reaction, whilst the latter generally does so at ordinary dilutions.[2] Of the bacilli tested only one of the present series gave a typical reaction with a dilution of one in 50, whilst three other cultures exhibited loss of movement but no typical clumping. The bacilli which gave a typical reaction were taken from the case of carcinoma of the bladder; they in all other respects behaved as members of the Escherich group.

TABLE II.—*Cases in which the Bacillus Coli was Present.*

Disease.	Hours after death.	Organs examined.	Organisms found.
Peritonitis, middle-ear disease, and pneumonia	12	(*a*) Lung and ear. (*b*) Peritoneum.	(*a*) Diplococcus. (*b*) Bacillus coli.
Gastric ulcer and chronic nephritis ..	18	(*a*) Kidney. (*b*) Spleen.	(*a*) Sterile. (*b*) Bacillus coli.
Enteric fever and pneumonia	?	Spleen and right apex.	Bacillus coli.
Enteric fever	20	(*a*) Spleen. (*b*) Liver.	(*a*) Bacillus coli. (*b*) Sterile.
Gastric ulcer and perisplenic abscess	34	Spleen.	Bacillus coli.
Enteric fever, pneumonia, and middle-ear suppuration ...	36	(*a*) Lung. (*b*) Ear, kidney, and spleen.	(*a*) Bacillus coli and staphylococcus. (*b*) Bacillus coli.
Infantile diarrhœa and pneumonia ...	24	Spleen.	Staphylococcus and bacillus coli.
Ulcerative colitis ...	30	(*a*) Liver. (*b*) Spleen.	(*a*) Bacillus coli. (*b*) Sterile.
Morbus cordis and chronic peritonitis	31	(*a*) Kidney. (*b*) Liver.	(*a*) Sterile. (*b*) Bacillus coli.
Hydatid of the liver and suppuration of the gall-bladder, &c.	26	Kidney and gall-bladder.	Bacillus coli.
Marasmus	20	Liver and spleen.	Bacillus coli.
Pleurisy and ascites	27	(*a*) Spleen. (*b*) Liver.	(*a*) Sterile. (*b*) Bacillus coli.
Carcinoma of the bladder	24	Spleen.	Bacillus coli.
Alcoholism, fatty liver	18	(*a*) Spleen and liver. (*b*) Kidney.	(*a*) Sterile. (*b*) Bacillus coli.
Acute peritonitis ...	24	Peritoneum.	Bacillus coli and bacillus mesentericus, &c.
Sarcoma of the stomach	24	(*a*) Spleen. (*b*) Kidney.	(*a*) Sterile. (*b*) Bacillus coli.
Intussusception ...	—	Kidney.	Bacillus coli.
Chronic nephritis ...	24	Kidney.	Bacillus coli.
Acute phthisis... ...	30	(*a*) Spleen. (*b*) Kidney.	(*a*) Bacillus coli. (*b*) Staphylococcus pyogenes aureus.
Pneumonia	20	(*a*) Lung. (*b*) Spleen.	(*a*) Pneumococcus and bacillus coli. (*b*) Pneumococcus.

It will be seen from Table II. that it is comparatively rare to find other organisms associated with bacillus coli in the same tissues. Beco has shown this to be due to the fact that after death the abundant growth of bacillus coli tends to extinguish any other forms which may originally have been present. This is a point of practical importance, for the post-mortem discovery of bacillus coli in a suppuration might lead to the supposition that this was the cause of the lesion, whilst the true determining cause may have been pyogenic cocci which have since perished. The finding of bacillus coli after death does not warrant the conclusion that it was the exciting cause of the lesion during life. It seems probable, too, that pure cultures of bacillus coli obtained from suppurations during life may in the same way lead to erroneous diagnosis. It is noteworthy that in 14 of these cases an intestinal lesion existed which might possibly have been the channel of infection. Of the remaining six cases 13, 14, 16, and 18 had abdominal viscera affected, 19 and 20 had no abdominal lesions. A culture of bacillus coli given to me by Mr. F. Wallis Stoddart who obtained it direct from Escherich's laboratory has been of much service in the work of distinguishing between the various coliform bacilli.

With regard to enteric fever (six cases) bacteriological examination for the detection of the Erberth-Gaffky bacillus was only successful in two cases, in both of which it was found in the spleen 24 hours after death. The method of isolation adopted was that of halo colonies, as recommended by Mr. Stoddart.[3] The other four post-mortem examinations were conducted from 24 to 36 hours after death and the cultures showed the wide and general distribution of bacillus coli which in one case was found in the kidney, in consolidated lung, and in a middle-ear suppuration. To ensure success cultures for the discovery of Erberth's bacillus should be made as soon as possible after death, preferably from the spleen. For differentiation from coliform bacilli the tests relied on were Widal's reaction and the non-production of indol, of gas-bubbles, or of clot in milk.

The second of the diphtheria cases (see Table 3), although diagnosed both clinically and at the post-mortem examination as diphtheria, was probably a membranous laryngitis of coccal origin. Klebs-Löffler bacilli were not present in either ante- or post-mortem cultures. The presence of the specific bacillus in the consolidated lung of three of the cases points to the possibility that the pneumonic condition may depend as much upon their presence as upon that of pneumococcus or of pyogenic organisms. The futility of purely local treatment of the disease is demonstrated by the presence of Klebs-Löffler bacilli in the enlarged cervical glands. Kanthack and Stephens[4] say that this is a common occurrence. They found also the organism present in pneumonic lung in 100 per cent. of cases, in the kidney in two out of three cases, and in the spleen in 10 out of 21 cases. In both of the cases mentioned above in which the spleen was examined the cultures remained sterile. During the progress of a case of diphtheria in life there is a tendency as convalescence approaches for the bacilli to alter in character, to become shorter, uniformly staining, and

TABLE III.—*Cases of Diphtheria.*

Hours after death.	Organs examined.	Organisms found.
21	(*a*) Lung. (*b*) Cervical glands.	(*a*) Streptococci, Klebs-Löffler bacilli (short), cocci, and bacilli. (*b*) Streptococci and staphylococci and short *Klebs-Löffler* bacilli.
12	(*a*) Larynx. (*b*) Lung. (*c*) Spleen.	(*a*) Short bacilli not resembling bacillus Klebs-Löffler, staphylococcus aureus. (*b*) Streptococcus, staphylococcus aureus and citreus. (*c*) Sterile.
12	(*a*) Lung. (*b*) Spleen.	(*a*) Staphylococci and streptococci, Klebs-Löffler and other bacilli. (*b*) Sterile.
28	Fauces, bronchus, and lung.	Klebs-Löffler bacilli (short) and staphylococcus pyogenes aureus.

---

[2] Durham: THE LANCET, Jan. 15th, 1898.

[3] Journal of Pathology and Bacteriology, June, 1897.

[4] Ibid.

generally atypical. This change was marked in all three of the cases examined, alike in the bacilli obtained from the membrane and in those cultivated from the tissues.

TABLE IV.—*Pyogenic or other Organisms.*

Disease	Hours after death	Organs examined.	Micro-organisms.
Ulcerative endocarditis ...	20	Kidney, spleen, and heart.	Staphylococcus pyogenes albus.
Empyema ...	31	Spleen.	Ditto.
Retroverted gravid uterus, cystitis, &c. ...	21	Spleen.	Staphylococcus citreus.
Acute infective osteomyelitis ...	12	Spleen, operation wound, and pleuritic abscess	Staphylococcus pyogenes aureus.
Traumatic peritonitis	12	Peritoneum	Staphylococcus
Malignant disease of the pancreas ...	20	(a) Spleen. (b) Liver.	(a) Bacilli (?) with spores (b) Sterile

One or other variety of staphylococcus (see Table 4) was most commonly developed. This is of interest in connexion with such diseases as ulcerative endocarditis and acute infective osteomyelitis in which the value of treatment by anti-streptococcic serum might be tested.

Clifton, Bristol.

RECOVERY AFTER BULLET WOUND OF THE HEAD AND DESTRUCTION OF BRAIN TISSUE.

BY ROBERT FENNER, L.R.C.P. EDIN., M.R.C.S. ENG.,

LATE SURGEON TO THE CROMER COTTAGE HOSPITAL.

ON the evening of July 10th, 1897, a man, 42 years of age, who was watching some youths at revolver practice, was accidentally shot from a distance of two yards. Arriving on the spot about 30 minutes subsequently I found him insensible, breathing slowly and somewhat heavily but not stertorously. His pupils were dilated and did not react to light. He was bleeding from the mouth and blood was oozing from the nose. At the back of the head, about one and a half inches to the right of the middle line and two inches above a line touching the upper margin of the external auditory meatus, there was a contused somewhat clean-cut wound from which blood was oozing and brain matter protruding. Having cut the hair and carefully cleansed and dressed the wound, rendering it as aseptic as possible, I caused him to be conveyed to the Cromer Cottage Hospital, a distance of two and a half miles. On admission he was practically in the same condition as above described but the pulse was slower and scarcely perceptible. Under an anæsthetic and with the assistance of Mr. H. C. Dent I exposed the wound by a large crucial incision through the scalp, turning up the four flaps well out of the way. Having thoroughly irrigated the wound and removed the protruding brain substance I found a circular and jagged hole in the skull admitting the little finger to the first joint. There was much splintering of the inner table and I could feel several large splinters of bone but no bullet even with a probe, although I could follow its track in a direction pointing to the right margin of the left orbit until the probe impinged upon hard bone. I now applied a large trephine and removed a circle of bone, taking in as much of the bullet wound as possible. Having removed several fragments of bone I made a careful examination of the track with my finger, passing it as far as I could reach into the cerebral substance, but I did not reach the bullet nor could I feel it with a long probe. The wound was copiously irrigated with a corrosive sublimate solution (1 in 4000), the nozzle of the irrigator being passed well into the brain, the flaps were sutured, and a small drainage-tube was left in position. The patient passed a quiet night but remained unconscious, blood continuing to ooze from the nose and mouth. On the following morning (July 11th) he had partially regained consciousness but was irritable and was aroused with difficulty. The pulse-rate was 52 and the respirations were 16. Hæmorrhage continued from the nose and mouth and the eyelids on both sides were much swollen. The next day the patient remained in an irritable condition, taking nourishment with difficulty. He was very restless and complained of pain in the head when questioned. The temperature was 101° F.; the pupils were equal but not reacting to light. The wound was dressed. There had been much oozing of blood and as the flaps were bulging two stitches were removed. On July 14th the temperature was 100°. Both eyes were ecchymosed. The bleeding from the nostrils and mouth had ceased. The pupils were equal and reacting to light. The pulse was 54. The patient was still irritable. Much brain substance was removed with this and subsequent dressings.

The patient remained in the same irritable condition until July 18th when he spoke rationally and could recall past events. He still complained of headache and was very drowsy and roused with difficulty. He had complete control over his bladder and bowels; his retinæ were examined and found to be normal, the reflexes were present and normal, and his senses of smell and taste were unimpaired. His temperature remained at 100° or over until July 21st when it gradually reached the normal. Bleeding from the nose ceased and by July 28th ecchymosis of the left upper eyelid alone remained. The patient gradually recovered strength and although somewhat irritable and childish he remembered past events perfectly and was quite rational. The hernia cerebri gradually became covered with healthy granulations and was completely healed by August 20th, at which date he left the hospital.

One year after the accident—viz., in July, 1898—the patient suffered from a slightly ataxic gait and an inability to see the left half of objects but otherwise he seemed none the worse for the injury.

This case illustrates the great amount of damage which can be borne by the cerebral substance provided the floor of the fourth ventricle and the sinuses are left intact. The bullet must have been flattened and irregular, having passed through a felt hat and the skull before ploughing up the brain substance. The course of the bullet was slightly upwards and to the left and the amount of bleeding from the nose and mouth and into the soft tissues surrounding the eyes point to the great damage sustained by the anterior fossa of the base of the skull. Although the chances of recovery appeared to be *nil* I trephined at once in order to anticipate tension and for the purpose of effective antisepsis and drainage.

I heard from the patient at Christmas, 1898—18 months after the accident—that with the exception of the partial loss of vision referred to he was completely restored to health and able to carry on his vocation. Dr. Johnson Taylor of Norwich kindly examined the patient's eyes and writes: "Your patient has left lateral hemianopsia due in all probability to an injury to the right optic tract or possibly to an injury to his right visual centre in the occipital lobe. The right half of each field and the central visual activity of each eye are normal. He reads $\frac{6}{6}$ with either eye and his accommodation is good. The ophthalmoscope shows a normal state of each fundus and the movements of the globe are normal; no other of his special senses seem in the least affected."

New Cavendish street, W.

THE INFLUENCE OF RAINFALL ON BERI-BERI.

BY P. N. GERRARD, M.D. DUB.,

DISTRICT SURGEON, ULU SELANGOR, FEDERATED MALAY STATES.

THE prevailing opinion amongst so many as I have had the pleasure of meeting of the members of the profession practising in the Malay Peninsula, where this disease causes such a very large number of deaths yearly, seems so much in favour of the supposition that cases of beri-beri occur more frequently during or after a wet month or that the severity of the cases is increased after wet weather that I have been led to collect the cases occurring in my district (Ulu Selangor, Malay States) for the past seven years. I have constructed a chart of the rainfall and beri- [illegible] for analysis and I hope to elicit remarks from other medical men who have had to deal with this most interesting and, I think I may say, badly understood disease. The total number of cases in the chart amounts to 2422, extending over 84 months from February, 1891, to December, 1897, inclusive.

Calling the months in which a rise or fall of rainfall was accompanied by a similar rise or fall of beri-beri admissions, "Positive" evidence, and the contrary, "Negative," I obtained the following figures:—

Months.	Positive.	Negative.
6 Januaries	3	3
7 Februaries	1	6
7 Marches	3	4
7 Aprils	3	4
7 Mays	3	4
7 Junes	4	3
7 Julys	5	2
7 Augusts	2	5
7 Septembers	4	3
7 Octobers	4	3
7 Novembers	0	7
7 Decembers	1	6
Totals	33	50

This we may, I think, fairly consider as our first contradiction to the original proposition that "the rainfall influences beri-beri or the cause of beri-beri." Of the 83 months in this list we have only 33 showing positive evidence as against 50 showing negative; some of these, too, show such ill-balanced proportion that they may be fairly excluded, as is shown in the following table*:—

In June, 1891, beri-beri shows a fall of 1 admission and rainfall 12 in.
" July, 1892, beri-beri " " 2 cases and rainfall 10 inches.
" June, 1895, beri-beri " " 13 cases and rainfall 1 inch.
" May, 1896, beri-beri " " 5 cases and rainfall 8 inches.
" February, 1897, beri-beri shows a *fall* of 23 cases and rainfall 2 in.
" October, 1893, beri-beri shows a rise of 4 cases and rainfall 10 in.

* The word "fall" in this table means diminution both with regard to beri-beri and rain—e.g., in June, 1891, one case less of beri-beri was admitted than in the preceding month and 12 inches less rain fell than in the preceding month.

Deducting these cases from the positive evidence we get 27 months positive, six months neutral, and 50 negative, and, in fact, these six neutral may be treated as negative evidence. As an example of how I have arrived at the positive + or negative – evidence I quote in the following table the year 1892 as a sample, 1891 being one month short (where beri-beri rises and rainfall also rises the evidence is positive, the contrary negative):—

Month.	Evidence.	Beri-beri.	Rainfall.
January ...	Positive	Fell 32 to 16 cases	Fell 28 to 13 inches
February ...	Negative	" 16 " 13 "	Rose 13 " 15 "
March	"	Steady (13 cases)	" 15 " 20 "
April	"	Rose 13 to 17 cases	± 20 inches
May	"	" 17 " 42 "	± 20 "

The next point of contradiction I wish to draw attention to is that during the seven years under consideration the months in which the greatest amount of rain fell were not the months on which the greatest number of admissions took place, nor were the months next following the heaviest rainfall the correspondingly highest in admission except in one case—namely, in the seven Decembers during which taken together 99 inches fell, followed in six Januaries by a total of 232 cases, 232 being the fourth highest total of admissions and 99 the fourth highest of rainfall; this is a sop to the supporters of the "after rain beri-beri increase" theory, but it has not very much weight when it is considered that in the case of the other months (seven of each), altogether 70 months out of a possible 83, the highest rainfall does not correspond with highest beri-beri; nor is highest rain followed the next month by beri-beri. The highest rain occurred in seven Octobers, accompanied by the seventh highest number of admissions of beri-beri and followed by the second highest number of admissions in seven Novembers. The second highest rain occurred in the seven Aprils accompanied by the fifth highest beri-beri list and followed immediately by the third highest beri-beri list in the seven Mays. The third highest (Novembers) rain accompanies the second highest beri-beri and is followed by the highest beri-beri (Decembers). The fourth maximum rain (Decembers) accompanies the highest and is followed by the fourth maximum beri-beri. The fifth maximum rain accompanies the third highest beri-beri and is followed by the ninth beri-beri; the sixth rainfall accompanies the eleventh beri-beri and is followed by the seventh beri-beri; the seventh rainfall accompanies the ninth beri-beri and is followed by the tenth beri-beri; the eighth rainfall accompanies the sixth beri-beri and is followed by the fifth beri-beri; the ninth rainfall accompanies the twelfth beri-beri and is followed by the eleventh beri-beri; the tenth rainfall accompanies the tenth beri-beri and is followed by the twelfth beri-beri; the eleventh rainfall accompanies the eighth beri-beri and is followed by the sixth beri-beri; the twelfth rainfall accompanies the fourth beri-beri and is followed by the eighth beri-beri. The maximum monthly rainfall for the seven years was in the following order: first Octobers, second Aprils, third Novembers, fourth Decembers, fifth Mays, sixth Septembers, seventh Junes, eighth Marches, ninth Augusts, tenth Julys, eleventh Februarys, and twelfth Januarys; whereas the maximum beri-beri admittances were in first Decembers, second Novembers, third Mays, fourth Januarys, fifth Aprils, sixth Marches, seventh Octobers, eighth Februarys, ninth Junes, tenth Julys, eleventh Septembers, and twelfth Augusts. The order of merit of the years with regard to rainfall and beri-beri is shown in the following table:—

—	The wettest year.		Beri-beri admission order.		
1	1891	250 in. (highest)	1891	121	7 (lowest)
2	1892	178 inches	1892	262	4
3	1895	123 "	1895	428	3
4	1893	111 "	1893	242	5
5	1894	110 "	1894	204	6
6	1897	109 "	1897	445	2
7	1896	104 in. (lowest)	1896	700	1 (highest)

In 1892 the district began to show signs of waking up and mines began to be opened. Since this time the cases have steadily mounted until 1896, falling a little again in 1897. Through the courtesy of Messrs. Grey and Thomson of the district office I have had access to the district land books and have found out the amount of land alienated by Government for mining purposes in each year as follows:—

Year.	Land alienated.	Order.*	Beri-beri.	Order.*
1891	None recorded	—	121 cases	7 (lowest)
1892	194 acres	6	262 "	4

1896	840 "	3	700 "	1
1897	678 "	4	445 "	2

* The figures in these columns indicate the relative position of the years 1891-1897 as regards the amount of land alienated and the number of cases of beri-beri.

The fact that the majority of miners are Chinese who very rarely open the ground at once, usually felling the jungle and then waiting for two years more or less before starting mining, coupled with the fact that everyone recognises that the district has become much busier in the last few years, will cause these figures to throw some light on the subject, although the amount of land alienated any given year does not bear any direct proportion to the number of cases that year. Allowing the usual two years for the land to lie unmined we find from the figures of the alienation of land that 1895, 1896, and 1897 ought to have produced the highest number of cases, and actually that is so, for during the years 1893, 1894, and 1895 2201 acres were alienated out of a total of 3813, and during the years 1895, 1896, and 1897 1573 cases of beri-beri occurred out of a total of 2422, considerably over half the amount of total land alienated and well over half the total number of cases in the seven years.

One more fact may be culled from the months in which the greatest amount of rain fell—viz., that they do not correspond with the highest beri-beri admissions in their individual position which may be seen on reference to the following table:—

Year.	Rainfall.		Beri beri.	
	Maximum.	Minimum.	Maximum.	Minimum.
1891	October, 54 in.	March, 6 in.	December, 32 cases.	February and October, 5 cases
1892	June, 23 in.	August, 7 in.	May, 42 cases.	February and March, 13 cases
1893	October, 13 in.	March, 3 in.	December, 35 cases.	July, 7 cases
1894	April and December, 14 in.	February, 1 in.	April, 34 cases	September, 5 cases
1895	October, 26 in.	January, 1 in.	December, 74 cases	February, 15 cases
1896	October, 15 in.	January and May, 2 in	November, 75 cases	June, 36 cases
1897	December, 20 in.	July, 5 in.	January, 78 cases	July and December, 20 cases

It is also worthy of notice that the greatest number of admissions in any month for the several years occurred in 1891 in December, in 1892 in May, in 1893 in December, in 1894 in April, in 1895 in December, in 1896 in November, and in 1897 in January; and the highest rainfall each year occurred in 1891 in October, in 1892 in June, in 1893 in October, in 1894 in April and December, in 1895 in October, in 1896 in October, and in 1897 in December. From this may be seen that although four Octobers out of seven have shown the maximum rainfall, yet October does not occur in the beri-beri list of highest admittances and the month following—that is, November—only once.

These facts, coupled with the universal experience of the miners—namely, that when the mines are opened a certain large proportion of men will get beri-beri and a comparatively small number suffer from severe malarial fevers—seems in my opinion to point to the cause of the disease being in the soil or perhaps to its requiring the presence of malarial conditions or even parasites for its proper development.

[Dr. Gerrard next recapitulates the existing theories as to the etiology of beri-beri, but owing to the pressure on our space we have omitted this part of his paper. We have omitted his chart because the tabular statements make his arguments quite clear.]

It is beyond my province here to deal with such interesting points as the initial symptoms, the physical signs, progress, diagnosis, and treatment, all of which sub divisions of this powerful and obscure disease require separate study, deep and honest, careful and concise, before we can hope to arrive at a true conclusion. I can only express a wish that the fact of its independence of meteorological vagaries may help to put us on our way to the commencement of that study which will begin on that date on which the cause is brought to light.

Since writing the above I have cultivated from the blood of an acute case of beri-beri a micrococcus somewhat similar to one described by Pekelharing and Winkler, but not so irregular in size. I am forwarding slides to the School of Tropical Medicine. No bacilli were to be found on the plates or in tubes. I may also mention that the figures for 1898 endorse this argument against the influence of rainfall on this disease.

Ulu Selangor, Federal Malay States.

BERKELEY HOSPITAL.—The annual meeting of the managerial staff of this hospital was held on Feb. 1st under the presidency of Lord Fitzhardinge. The medical report stated that 75 cases had been admitted during the past year. The financial statement showed an adverse balance of £61 at the end of the year.

DORSET COUNTY HOSPITAL.—The annual meeting of governors, managers, and subscribers to the Dorset County Hospital, Dorchester, was held on Feb. 2nd under the presidency of Captain Acland. The report stated that during the past year 268 in patients had been admitted and 868 out-patients attended. The financial statement showed that the income from all sources amounted
and the expenditure to £2347.

A NOTE ON "CASES OF PHTHISIS WITH PECULIAR CARDIAC PHYSICAL SIGNS."

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN; JOINT LECTURER ON MEDICINE IN THE MEDICAL SCHOOL OF ST. GEORGE'S HOSPITAL.

UNDER the heading of "Cases of Phthisis with Peculiar Cardiac Physical Signs" two cases of great interest were recently reported in THE LANCET by Dr. Hale White[1] and by Mr. W. Southwick Willmore[2] which had until now escaped my notice. The physical signs noted were those of a great displacement of the heart to the right, yet at both necropsies the heart was found to be normal and *not* displaced. Both observers seem to accept the position that the displacement which they had diagnosed must have been apparent only, the cardiac sounds being conveyed by consolidated tissue, though they are at a loss to account for the impulse which in one case was felt and in the other was seen as well as felt in the right chest, and the conclusion arrived at is that "we must not assume that when the heart's impulse is seen and felt far on to the right side of the chest the organ is necessarily dragged or pushed over or altered in size." As any interpretation of the kind suggested might tend to shake that trust in our clinical methods of diagnosis which it is desirable that we should uphold, the time may not be thought to have passed for this reference to the cases and for an attempt to rid them of their mysterious character and to reconcile statements which were probably only in appearance contradictory. The clinical observations described are to my mind conclusive evidence of the existence during life of a considerable displacement of the heart to the right in both cases; but it is conceivable that this displacement could not be readily demonstrated by the ordinary post-mortem examination.

Cases of this sort occur from time to time among the large number of cases in which fibroid excavating disease of the right lung tends to displace the heart more or less. When at the same time the left lung and the heart are fixed by adhesions the right side of the thorax falls in. If the right chest should not fall in this must be due either to a considerable emphysematous distension of the right middle and lower lobes or, failing this, to the encroachment of the heart and of the left lung into the right chest. It is therefore clear that the cardiac displacements which are considerable and horizontal belong more especially to the group of cases in which, whilst the thorax remains symmetrical, the right lower lobes are not only free from distension but are often themselves the seat of destructive lesions such as those reported in one of the two cases. Precisely similar cases have come under my own notice.

In January, 1891, closely adjoining beds were occupied by two patients under my care with destructive lesions in the right lung in whom the heart was much displaced, the cardiac dulness and impulse occupying in the right chest the position which normally belongs to them in the left. One of these patients, suffering from extensive bronchiectasis of the right lung, in whom Mr. Bennett had resected the right ninth rib at my request but had failed to obtain any discharge of pus, was exhibited at the Medical Society of London[3] under the heading of "Dexiocardia"—a term properly restricted to the exceedingly rare cases in which the heart alone is congenitally transposed to the right, the other viscera not being transposed. Both patients died and were examined after death. In the *first case* I happened to be prevented from witnessing the beginning of the necropsy and I was met on my way to the *post-mortem* room by a report that whilst the right lung was extensively excavated the relations of the heart were absolutely normal—a report which, not entertaining any doubt as to the reality of the displacement during life, I received with surprise and not without some reservation as to its retrospective significance. In our Post-mortem and Case Book (No. 64, 1891) may be seen facing each other two equally trustworthy and accurate records, one describing the heart as it lay in its normal position, the other setting forth the clinical evidence of great displacement of the heart into the right chest. I never ceased to believe that the heart had been contained within the right chest before the chest was laid open and that the displacement might have been visible had the pericardium been opened from the abdomen before opening the chest. The second necropsy,[4] that of the case of bronchiectasis, showed the cardiac displacement without any difficulty, thanks to the powerful adhesions which retained the heart in the position which it had occupied during life; and this confirmed me in the view which I had taken of the first. Both cases were, practically speaking, identical in their clinical signs, and the pulmonary lesions were closely analogous—viz., considerable destruction of pulmonary tissue and fibrosis involving the posterior part of the upper lobe and extending into the inferior lobe almost to the base. The leading difference was that in one case the right pleuro-pericardial adhesions were continuous with the retracted fibrous tissue of the lung, in the other they were not. If this source of fallacy be borne in mind by the pathologist he may so conduct the operation as to demonstrate the actual condition. But even should the heart have been allowed to slide back unobserved into the left chest, owing to the admission of air into the pleuræ, it may not be impossible to reconstruct the true pathological anatomy of the thoracic contents. Thus in the cases reported by Dr. Hale White and by Mr. Southwick Willmore, both of which, as is essential for the production of the fallacy in question, were *free from collapse of the right thoracic* wall, a considerable proportion of the total capacity of the right half of the thorax corresponding to the extensive destruction of lung tissue had to be accounted for. This surplus of space we must assume to have been filled by the heart since it could not have been occupied by the right lung owing to the pneumonic condition of the lower lobes in one of the cases and to their diseased *and airless condition in the other.* I would therefore suggest for both these instances the same explanation which I had adopted at the necropsy on my own case—viz., that when the sternum and costal cartilages were removed the heart must have dropped backwards by its own weight and to the left owing to the partial subsidence of the over-stretched left lung. The heart would then have been seen in apparently natural lateral contact with the right lung; yet by reapplying the sternum it might have been possible to show that the damaged lower right lobes, practically incapable of expanding, could not have completely tenanted the vacated right parasternal region.

---

[1] THE L 19th,
[2] THE LAN

Taking, then, the view that these were instances of *mobile hearts held in the right chest by atmospheric pressure* owing to extensive destruction of the right lung without compensating collapse of the chest wall, it may perhaps be suggested to clinicians that skiagraphy might place their diagnosis of displacements of the heart beyond any chance of scepticism, and to pathologists that they might in investigating cases of this kind modify their method of section in some suitable manner likely to afford a view of the heart before there had been any possibility of its relations having been disturbed.

Curzon-street, Mayfair, W.

A NEW PREPARATION FOR RAPIDLY FIXING AND STAINING BLOOD.

By LOUIS JENNER, M.B., B.CH. OXON., M.R.C.P. LOND.

(From the Clinical Laboratory, St. Thomas's Hospital.)

MOST persons will agree that the only justifications for introducing a new histological stain are (1) that it should demonstrate something new, or (2) that it should demonstrate something more plainly and readily than before, or (3) that it should be a simpler method than that in general use. It is claimed for the following new compound blood stain that it at any rate fulfils the last two conditions. The stain is a single solution, easy to make up, which keeps well, which will fix and stain ordinary blood films in two minutes, and which demonstrates with perfect clearness and in well-marked contrasts red blood discs, blood platelets, the nuclei of white blood cells, the fine granules of the polymorphonuclear leucocyte, coarse oxyphil granules, basophil granules, and when present, erythroblasts; bacteria, the malaria parasite, and filariæ. It has been primarily designed for bedside work where rapid and certain methods are the main consideration.

In absolute alcohol we have one of the most reliable fixatives known, and eosin and methylene blue possess the requisite properties for demonstrating all the ordinary characteristics of normal and of pathological blood. Eosin itself, however, cannot under ordinary circumstances be made to stain certain cell granules and for this purpose various combination stains have been used; of these the most generally used are the Ehrlich-Biondi and Ehrlich's later triacid. These, however, are undoubtedly troublesome to use and require special fixing methods. When to a solution of eosin some solution of methylene blue is added a precipitate falls—brilliant grass-green crystals if alcoholic solutions and alcohol-soluble eosin (Grübler) are used, but amorphous and of a dark metallic-green colour if watery solutions and water-soluble eosin are used.

The eosin methylene blue mixtures at present in use, as far as I know them, are designed with a view to avoiding the precipitates which form when solutions of these dyes are mixed or after they have been kept a short while. These precipitates are, I believe, compounds of eosin (acid) and methylene blue (base).

The brilliant grass-green crystals obtained from alcoholic solutions are very sparingly soluble in alcohol in the cold, but more soluble in hot alcohol, from which they can be re-crystallised in the same form. That they represent a definite compound body is, I think, rendered probable by the fact that the same crystals are obtained, though in varying amounts, however the proportion of the original ingredients is varied, and that the crystals so obtained have identical melting points—viz., 227° C. taken on the surface of mercury. The suggestion to test them in such ways I owe to Mr. E. White of St. Thomas's Hospital. These crystals from their sparing solubility in alcohol are not useful as a blood stain without previous fixation of the film. They are, as a matter of fact, soluble in chloroform and in aniline oil, the solutions in each case being of a dark violet colour.

The amorphous precipitate obtained from watery solutions of the two dyes is in its turn very sparingly soluble in water, but in alcohol it gives a blue solution with strong green fluorescence; it is more soluble in methyl alcohol. It is such a solution which I find to work admirably as a blood film fixative and stain. It is made up in the following way. Equal parts of a 1·2 per cent. to 1·25 per cent. solution of Grübler's water-soluble eosin, yellow shade, in distilled water and of a 1 per cent. solution of Grübler's medicinal methylene blue, also in distilled water, are mixed together in an open basin (not in a flask) and thoroughly stirred with a glass rod. The mixture may with advantage be left for 24 hours. It is next filtered and the residue is dried either in the air or more quickly in an incubator or water oven. I have dried it at 55° C. without harm. When quite dry the residue is scraped off the filter-paper and is powdered. It is then shaken up with distilled water and washed on a filter, when the washings should be of a thin dirty-purplish colour. Finally, it is again dried and powdered and may be stored in suitable bottles. For use, thoroughly shake up 0·5 gramme of the powder in 100 cubic centimetres of pure methyl alcohol (E. Merck "for analytical purposes")[1] and then filter. The solution keeps well.

Cover-glass preparations are made in the ordinary way and on to them as soon as the films (which should be extremely thin) are dry a few drops of the staining and fixing solution are poured, no previous fixation being required; it should, however, be noted that it is essential to the correct working of the stain that the cover-glasses used should be absolutely clean and should have no trace of acid or alkali on them. After they have been cleaned and well washed in distilled water they should be kept in absolute alcohol only. The specimen is covered with a watch-glass to prevent evaporation and consequent precipitation. In from one to three minutes the stain is rapidly poured off and the specimen is at once rinsed in *distilled* water till the film has a pink colour which usually occurs in from five to 10 seconds. It is then dried either very high up over a flame or (better) by agitation in the air and is mounted in xylol balsam.[2]

---

[4] Post-mortem and Case Book, No. 64, 1892.

[1] Certain other brands work quite well, but to most of the less pure preparations it is necessary to add absolute ethylic alcohol in greater or less amount to reduce their acidity and to obtain proper *fixation.*

The red discs are of a terra-cotta colour; the nuclei of the white corpuscles are blue; the platelets are mauve; the granules of the polymorpho-nuclear white cells and of myelocytes are red; the granules of the basophils (mast cells) when present are dark violet; and bacteria, filariæ, or malaria parasites are blue. If the specimen has been washed in tap water and not in distilled water the red colours are more pronounced and the blue of the white cell nuclei is almost washed out, while the dark blue of the bodies of the smaller hyaline white cells (lymphocytes) stand out in strong contrast to the now pale nucleus.

It seems to me that the results obtained by this method rather point to the granules of the polymorpho-nuclear leucocytes being basic—i.e., oxyphil—a fact which seems still disputed by some.

The differential staining results from the decomposition of the compound substance by the various elements of the blood, those parts which are acid combining with the basic colouring matter and those which are basic with the acid. That the stain is readily so split up is seen by adding weak acids or weak alkalies to such a watery solution of it as can be made—acids turning the solution blue and alkalies changing it to a pink, the stain acting, in fact, as a fairly delicate indicator. The same result is brought about by heating such weak watery solutions, which turn blue on warming, the original colour returning on cooling.

The stain may be equally well-made by dissolving the eosin and the medicinal methylene blue directly in absolute methylic alcohol and mixing them in the proportions given above—viz., 125 cubic centimetres of a 0·5 per cent. solution of the eosin and 100 cubic centimetres of a 0·5 per cent. solution of the medicinal methylene blue. Although this gives quite as good results the simpler method for ordinary practice is obviously to make a solution of the compound body which may be purchased in the solid state from Mr. R. Kanthack, 18, Berners-street, W., who also supplies the solution ready for use.

St. Thomas's Hospital.

NOTES ON A CASE OF RAPIDLY FATAL GLYCOSURIA IN A SUBJECT OF FRIEDREICH'S DISEASE.

By W. HARRIS BEST, L.R.C.P. LOND., L.S.A.

THE patient, a girl, aged 14 years, commenced at the age of seven years to suffer from difficulty in walking and loss of power in the legs and from that time the train of symptoms characteristic of Friedreich's ataxy slowly developed, following exactly the same course as in the case of a sister two years older. There was complete ataxic gait, with extreme talipes and loss of coördination in movements of the hands. Lateral curvature of the spine and certain involuntary movements of the head as well as complete absence of knee-jerks were other signs present. With reference to the family history, a great uncle on the father's side was said to have suffered from difficulty in walking at the age of seven years and this was followed in the course of time by paralysis of the lower limbs, but he lived to the age of 50 years. The father and mother were both healthy. The course of the patient's final illness was as follows. On August 23rd, 1898, whilst seeing another member of the household I was consulted for the first time with reference to the patient's indisposition. The mother had noticed her daughter getting thinner for the past fortnight—that is, since her return from a seaside holiday. By a curious coincidence the last case of diabetes which occurred in my practice came on immediately after the patient's return from his annual seaside holiday. On questioning her I found that there were marked thirst and polyuria. She got out of bed at least three times at night and each time passed a fair quantity of urine. The bowels were moved regularly every day, the tongue was covered with a light brown fur and was rather dry with red margins. The skin was dry and harsh. There was a fair colour in the cheeks which was diffused over the face though at times she was pale. Examination of the chest failed to find any lung disease. There was a slight mitral systolic bruit heard over the heart's apex but no displacement of the apex beat or other abnormality of the heart. She was emaciated. The pulse was 60 and fairly full and regular and the temperature was subnormal. The quantity of urine passed in 24 hours was about four quarts; it was of light colour but rather turbid and acid in reaction; the specific gravity was 1045. On testing with freshly prepared Fehling's solution the brick-red discolouration showed immediately; the dark brown, on boiling with liquor potassæ as in Moore's test, showed equally well. The same applied to the picric acid test, the discolouration in the latter being very opaque. There was no albumin in the urine. On the following day (the 24th) she was placed on diabetic diet, though allowed a small quantity of toast at first. A quarter of a grain opium pill was given three times a day and Vichy water two or three times daily. She took a good proportion of meat with plenty of fat among other things. On the 25th—that is, after one day's treatment—the more troublesome and obvious symptoms, such as thirst and languor, commenced to abate. On the 26th Dr. F. J. Smith was called in consultation. He confirmed the diagnosis and advised a continuation of the same treatment with the addition of 10-grain doses of sodium salicylate three times a day. He also agreed with the diagnosis of Friedreich's disease in both girls. Dr. Smith was much interested in the case and I am indebted to him for some valuable hints as to treatment, &c. On the 27th the improvement was maintained; less urine was passed and the patient had been only disturbed once during the night. Examination of the urine, however, showed little change On the morning of the 28th she appeared still to be improving and was quite cheerful. In the afternoon abdominal pain with some diarrhœa and sickness came on, much prostration resulting. These symptoms were followed in a few hours by sighing respiration, the breathing being deep and loud. There were extreme coldness of the extremities, small pulse, and all the signs of marked collapse accompanied with short paroxysms of dyspnœa, but the patient could very easily be aroused from the stupor. The acute bowel symptoms quickly subsided though slight vomiting still occasionally occurred. The odour of the breath was decidedly peculiar and suggestive of that described in text-books as accompanying diabetic coma. All the ordinary means of stimulation appeared to be useless though many were tried, such as mustard poultices to the chest and brandy, ether, and strychnine hypodermically administered. Though the pulse seemed to momentarily improve after giving by the mouth a strong solution of ammonia in small doses well diluted with cold water, this had to be discontinued through sickness and the bowel was too irritable to retain any saline solution which was injected. The patient was not delirious at any time; indeed, she retained consciousness to near the very end. She remained in this condition for three days, a certain amount of dyspnœa occurring up to the last. Unfortunately a post-mortem examination was not obtained.

In view of the paucity of our knowledge concerning the etiology and pathology of diabetes and of its association in this case with Friedreich's ataxy, the morbid pathology of which is comparatively well known, this case appeared to be worth recording though the absence of a post-mortem examination very considerably detracts from its possible value as a record. It is hoped that it may be of some little interest (brief and very incomplete as it is, partly through the unexpected and abrupt ending of the case), more especially to those engaged in investigating the nervous side of the origin of diabetes.

Remarks by Dr. F. J. SMITH.—This case seems to me to be well worthy of record because both diseases were so very distinctly marked. Both sisters I have since been given to understand have seen several eminent neurologists and, I believe, have been shown at societies as typical cases of Friedreich's ataxy, while about the glycosuria with acute diabetic coma there could be no doubt. To speculate on the advance of cord-sclerosis as affecting the nerves controlling visceral function would be rather futile when based on one case only, which may be but a coincidence, but should other similar cases be reported of a like nature this one would add considerable weight to the argument.

Ilford.

---

[2] If distilled water is not available tap water may be used provided the specimen be only momentarily immersed in it and then dried between filter-paper or rapidly over a flame. Pictorially such a specimen is not so perfect.

CHARING CROSS HOSPITAL.

TWO CASES OF PERFORATING GASTRIC ULCER; OPERATION; ONE RECOVERY AND ONE DEATH.

(Under the care of Mr. JOHN H. MORGAN.)

ALTHOUGH it is probable that the statistics of the operation for perforation of an ulcer of the stomach which are based on published cases do not exactly represent the true mortality, yet the results obtained from a consideration of a complete series of cases under individual surgeons go far to show that the mortality is much less than might have been expected. For instance, Mr. A. E. Barker[1] had three recoveries in seven cases and it may fairly be said that nearly 50 per cent. of the cases recover after operation. The two chief data on which the prognosis can most safely be based are, firstly, the length of time which has elapsed between the perforation and the operation; and secondly, the presence or absence of food from the stomach. It is extremely rare for recovery to follow if more than 24 hours have elapsed before the abdomen is opened. A. J. Cabot[2] has recently recorded a case in which the operation was performed 24 hours after the perforation occurred, but as the stomach was practically empty hardly any extravasation took place and recovery ensued, the opening having been sutured. An important point which is now being much discussed is the best method of cleansing the peritoneum in these and similar cases and the consensus of opinion is on the whole in favour of wiping rather than flushing. By neither method is it possible to remove all the extravasated material and micro-organisms are sure to be left; it is probable that the peritoneum can dispose successfully of a certain number of germs. Mr. Morgan's two very interesting cases form a welcome addition to those which we have recently published. In the first case eight hours intervened between the perforation and the operation, in the second a whole day, and this of itself would go very far to account for the fatal result in the latter.

CASE 1.—A woman, aged 27 years, had for some time suffered from dyspepsia and symptoms of gastric ulcer, for which she had been treated by Dr. Sapp who, however, had not been consulted for six weeks, when on Oct. 8th, 1897, the patient went for a walk in the suburbs and on returning she became very ill and Dr. Sapp was sent for and found her in a state of very severe collapse. She was at once conveyed to the hospital where she was seen by Dr. Willcocks who summoned Mr. Morgan, and it was decided to operate immediately. It was ascertained that some months previously she had vomited blood but had been able to resume and to continue her work. When seen she was in a condition of great prostration but fully conscious. The respirations were rapid and entirely thoracic. The abdomen was universally distended, the liver was not perceptible, and there were great pain and tenderness, especially in the left hypochondrium. The pulse was rapid, small, and compressible. The operation was performed at 1 A.M., eight hours after the presumed occurrence of perforation. An incision about two and a half inches in length was made in the mid-line between the ensiform cartilage and the umbilicus. Upon opening the peritoneum some gas escaped and a quantity of turbid fluid mixed with semi-solid food and curdled milk was sponged out. The stomach was then brought up to the edge of the wound and searched. Upon the anterior surface between the greater and lesser curvatures and nearer to the cardiac than to the pyloric end was found a small, ragged slit or perforation about one-third of an inch in length through which the contents of the stomach were exuding. The walls around this were considerably thickened over an area about one and a half inches in diameter. Eight Lembert's sutures of fine silk were passed which securely closed the slit in the stomach wall and four broader sutures were passed above these to draw the wall of the stomach closer together and to avoid tension upon its weakened part. The cavity of the peritoneum was then carefully wiped with hot dry sponges in every direction, particular attention being given to the space between the liver and the diaphragm, from which many particles of food were removed. The abdomen was then flushed with weak boric solution followed by hot water. When the peritoneal cavity had been again sponged dry the abdominal wound was united by interrupted sutures of fishing gut and a small indiarubber drainage tube was inserted at the lower end. After dusting with iodoform the parts were dressed with cyanide gauze and blue wool and an abdominal binder was applied. The patient passed a quiet night but vomited twice during the morning following. Nourishment was given by means of enemata of peptonised milk and eggs. The following day the pulse was 108, full and strong, and the temperature was 100° F. Pain in the region of the incision made breathing difficult, but there was no pain, distension, or tenderness in the other parts of the abdomen. The surface of the tongue was excessively foul but moist; the patient slept well. On Oct. 10th there was still pain in the region of the wound and she suffered from slight cough. The dressings were renewed and the tube was removed, a piece of iodoform gauze being inserted in its stead. Only a small amount of pure blood-stained serum exuded. During the next 10 days she made steady progress; the temperature sank to normal, the cough ceased, and the tongue slowly became cleaner. Thirst was excessive and on the eighth day small quantities of milk and eggs were given by the mouth. On the thirteenth day the temperature rose to 101° and pain was complained of. On dressing the wound a small collection of foul-smelling pus was evacuated in which were seen some shreds of coagulated milk which had been lodged between the skin and the muscles in the abdominal wound. The collection was entirely superficial and the parts were syringed out with boric lotion and a drainage of gauze was re-inserted. The temperature again became normal in three days and the abscess cavity closed. By slow degrees the patient resumed a normal diet and at the end of six weeks she was walking about. It was some time before she left the hospital, as she still suffered occasionally from dyspeptic symptoms and pain, and she remained under the care of Dr. Green, as it was feared that there might be some recrudescence of the old ulceration or that a fresh ulcer might arise. All symptoms, however, at length subsided, and she ultimately left the hospital in fairly good health.

CASE 2.—A woman, aged 27 years, was admitted to hospital on Feb. 7th, 1898. She had suffered from dyspepsia for more than a year and had been treated for gastric ulcer. In the previous August she had vomited some blood but no recurrence had taken place until the day before admission, when after carrying a tea-tray upstairs she suddenly became faint and felt severe pain in the region of the stomach and between the shoulders. She was put to bed and she soon brought up a small quantity of blood. A medical man who saw her ordered immediate removal to the hospital, where she arrived on the following afternoon. She was apparently a stout, ruddy, well-developed woman. She lay on her back with her legs drawn up, the abdomen being markedly distended and the muscles rigid, especially upon the left side. Pain was referred more particularly to the left iliac region; liver dulness was obliterated. The pulse was small, running, 156, and only faintly perceptible at the wrist. The respirations were 40; the alæ nasi were working. Her expression was anxious but consciousness was unimpaired. On the arrival of Dr. Bruce and Mr. Morgan it was decided that though the patient was desperately ill the only chance for her life lay in immediate operation. Ether was administered and an incision was made about one inch to the left of the middle line. On puncturing the peritoneum a quantity of very foul gas escaped and on enlarging the opening a large amount of turbid yellowish fluid containing clots of milk and some more solid contents of the stomach gushed out. The stomach was drawn up into the wound and an ulcerated opening was soon found. This was large enough to admit a finger; the edges were ragged and there was a considerable extent of surrounding induration. It was situated on the anterior surface at a short distance below the cardiac end So bad was the condition of the patient that this had to be dealt with as rapidly as possible but it was ultimately closed with six silk sutures inserted by means of curved needles, and a few Lembert's sutures were used to draw the neighbouring parts together and so to cover in the edges of the ulceration The peritoneal cavity was rapidly sponged and then flushed with hot boric lotion and hot water. The wound was closed as quickly as possible and every effort was made by means of injections of strychnia, enemata of brandy, and inhalations of oxygen to revive the patient, but she died a few hours after the completion of the operation The post-mortem examination showed acute universal peritonitis

[2] Boston Medical and Surgical Journal, August 11th, 1898, p. 134.

Remarks by Mr MORGAN —There were published in the "Mirror of Hospital Practice" during 1898 five cases of laparotomy for perforating gastric ulcer, four of which were successful It is to be feared that this does not represent the proportion of recoveries to operations performed, but it seems very desirable that successes and failures alike should be recorded in order that all details which may help to bring about successful results may be carefully considered As pointed out in the article in THE LANCET of Dec 31st, 1898, the prospects of success depend to a large extent upon the period which has elapsed between the actual perforation and the time when laparotomy is performed The symptoms of perforation are almost unmistakeable and little time need be wasted on the question of diagnosis On the other hand, there are conditions which may render even the most speedy operation almost hopelessly futile, such as the large size of the perforation itself, the previous state of the patient, and the nature and amount of the contents of the stomach which are poured out into the peritoneal cavity Such conditions are well contrasted and exemplified in the two cases narrated

LONDON TEMPERANCE HOSPITAL.

A CASE OF SEPTICÆMIA TREATED WITH ANTISTREPTOCOCCIC SERUM, RECOVERY

(Under the care of Dr LEONARD WILDE)

THE failure which has in so many cases attended the *injection of antistreptococcic serum in septicæmia* is chiefly to be attributed to its indiscriminate employment in all forms of septic infection It is essential that the presence of streptococci should be demonstrated, otherwise our knowledge of the value of this powerful therapeutic appliance cannot advance There is reason also to believe, as Dr Wilde points out in his remarks that all streptococci are not affected by the same variety of serum The case recorded below is very striking and the bacteriological evidence is very satisfactory In the present condition *of variation in* the quality of antistreptococcic serum it is always advisable to mention the source of the serum employed During 1898 we published several interesting cases of septic infection in which the antistreptococcic serum appeared to be of value [1] A case of great interest appeared in the *Therapeutische Monatshefte* of September, 1898, p 498, in which severe septic symptoms developed in a medical man who accidentally inoculated himself with pus from a boil Recovery was rapid and complete after injections of antistreptococcic serum

A youth, aged 18 years, robust and muscular, with a healthy personal and family history, was admitted under the care of Dr Leonard Wilde on August 19th, 1898 Five days before admission he had begun to suffer from vertical and occipital headache which had commenced without apparent cause and rapidly increased in intensity On admission he was conscious and able to answer questions but was somewhat apathetic and merely complained of severe headache A complete examination showed no organic *disease and no evidence of injury The* temperature was 101.6° F and the stools and urine were normal He remained in practically the same condition until August 26th when the pharynx and tonsils became swollen and inflamed and on Sept 2nd they were covered with a pultaceous and offensive exudation. A bacteriological examination of the secretions of the throat showed a complete absence of diphtheria bacilli but an almost pure cultivation of the micro-organisms belonging to the streptococci group An examination of the blood carried out by the Clinical Research Association gave negative results with regard to Widal's reaction for enteric fever, but streptococci were present in large numbers The patient was now in a very critical condition, his temperature was 104°, he was semi conscious, tremulous, passing everything under him, and seized with occasional convulsions, and it was evident that unless the noxious organisms circulating in the blood were destroyed without delay fatal results would occur Accordingly on Sept 3rd 10 cubic centimetres of antistreptococcic serum were subcutaneously injected every four hours It was observed that for a short time after each injection the patient rallied and the pulse improved, but this was not maintained until the following injection The dose was therefore doubled in quantity though reduced in frequency and eventually only 20 cubic centimetres were injected every 12 hours On Sept 5th considerable improvement was noted, the temperature had fallen to 101°, and the patient expressed himself as feeling better On the 10th pneumonic consolidation of the upper lobe of the right lung supervened, accompanied by violent delirium and high pyrexia The injections were, however, regularly continued until the 12th when, according to the report of the Clinical Research Association, the blood was pronounced to be sterile There was then reason to hope that no further development of the disease would occur and that only its effects remained to be dealt with The injections, which had now amounted to 345 cubic centimetres of the serum, were discontinued The patient was still in a precarious condition, superficial abscesses having appeared in many portions of the body and the condition of the right lung was throwing an additional strain on the heart The throat, however, began to clear, and on the 17th the temperature commenced to fall, reaching normal about the 20th After this he gradually improved, *though* convalescence was *somewhat* protracted owing to an attack of hæmaturia His recovery was eventually complete and he was discharged on Nov 16th He was seen again on Jan 15th, 1899, and with the exception of considerable pallor he appeared to be in good health

Remarks by Dr WILDE —This case is interesting as belonging to a class of disease about which there has been considerable controversy as to the efficacy of serum therapy when employed as a germicide It has not, I think, been claimed that antistreptococcic serum acts as an antitoxin as in the case of the antidiphtheritic serum but merely that it possesses bactericidal properties which may be applied in certain cases with a rational expectation of success Whether the patient recovered because of the administration of the serum or simply during such administration I have no desire to state, but the facts have been recorded as they occurred and those interested in the subject can form their own opinion The difficulty of successfully applying the antistreptococcic serum rests on the fact established by Van de Velde that there are several races of streptococci, none of which affords protection against the other, and until a serum has been obtained which includes the products of each race the success of the treatment will depend upon whether the organisms to be attacked are of the same race as those from which the serum injected has been derived

GLASGOW CENTRAL DISPENSARY

A CASE OF ACUTE TUBERCULOUS CHOROIDITIS FOLLOWING OPERATIVE TREATMENT OF TUBERCULOUS LESIONS IN A LIMB

(Under the care of Mr G H EDINGTON)

IT cannot be questioned that a surgical operation on a tuberculous lesion is a possible cause of a general diffusion of the disease, and there is little doubt that such a dissemination does occur, though very few cases appear to have been recorded; yet most surgeons must be able to call to mind cases which could be most easily explained on this supposition *Scraping* a tuberculous lesion with a sharp spoon seems to be more likely to give rise to general infection than any *other form* of operation In Mr Edington's very interesting case the interval (four days) between the operation and the *first manifestation* of anything wrong with the eye is rather short and we are inclined to agree that the choroidal lesion was not new

A boy, aged three years, was taken to the Glasgow Central Dispensary on April 14th, 1897, on account of an ulcerated condition of the left hand with swelling at the elbow and knee of the same side. The patient had been a fairly healthy child till he suffered from measles about two months before being seen at the dispensary. Either during convalescence or somewhat later a swelling appeared in the palm of the left hand. This was opened and had continued to discharge since. The time of the commencement of the condition of the knee and elbow was not known definitely. Since the attack of measles he had "failed" greatly according to his parents' statement. The mother was an apparently healthy woman, while the father was tall, well-built, and very robust. Two years previously he suffered when in the China seas from sudden blindness which lasted for a few weeks and then left him with apparently unimpaired vision. Besides the patient there had been one child who died when about a year old from what appeared to have been tuberculous meningitis. On examination the patient showed evidence of rachitic condition; this was chiefly marked in the head which was of the broad type. On the palmar surface of the left index finger and near the metacarpo-phalangeal joint there was an ulcer covered with a scab and surrounded by thickened tissues. The cubital gland was enlarged and softened and there was thickening of the lower half of the shaft of the humerus. The elbow-joint was free. The left knee presented synovial thickening giving the joint a globular appearance. On April 17th chloroform was administered and the palmar ulcer was scraped with Volkmann's spoon and found to be part of a tuberculous process involving the sheath of the flexor tendon of the index finger. The cubital gland was incised and watery pus was evacuated, followed by cheesy material, and a tuberculous membrane was removed by the spoon. Four days later the parts were dressed and looked well. There was, however, a dimness of the left eye, especially of the cornea. This was not present prior to the operation and it was thought that it might be a corneitis following an incautious dropping of chloroform. On the other hand, taken in conjunction with the enlargement of the lower end of the humerus, the probability of the corneal condition depending on syphilis was considered.[1] The child was therefore given one grain of mercury with chalk twice a day. By May 1st (a fortnight after the operation) the condition of the eye which was unimproved had become the leading feature of the case. There were then photophobia, enlargement of the eyeball (without tenderness), a greyish condition of the cornea, decided conjunctival injection, and some catarrh. Since the last note the patient had been very heavy and had lost his appetite. He was thinner, but the local conditions (knee, humerus, &c.) were no worse. On account of the progressive nature of the affection of the eye the child was sent to the Charlotte-street department of the Glasgow Eye Infirmary under the care of Dr. Maitland Ramsay. Dr. Ramsay found the condition to be one of purulent choroiditis and expressed the opinion that it was probably of tuberculous origin. He enucleated the eyeball on May 20th. The child made an uneventful recovery and was dismissed from the eye infirmary well as regards the orbit and with the wounds of the hand and elbow healed. The eyeball was examined by Dr. Leslie Buchanan and the choroid was demonstrated by him to be the seat of a tuberculous process.

---

[1] THE LANCET, Feb. 19th, 1898, p. 502, and March 19th, p. 779.

Pathological note by DR. LESLIE BUCHANAN.—The eyeball was found to be considerably enlarged by the formation of an ectasia of hemispherical shape at the upper and inner quadrant near the equator and measuring 14 millimetres across the base. On the globe being bisected by an oblique antero-posterior cut it was found that the cornea was clear and that the iris was free, having a good anterior chamber. The posterior chamber was abolished by total posterior synechia. The lens was of normal size, occupied the normal position, and was clear. There manifestly had been a moderately severe irido-cyclitis as both the iris and the ciliary body were covered by a layer of fibrinous exudation and there was a considerable amount of the same material present in the anterior chamber. The retina was totally separated from the choroid and was pushed tightly forwards against the lens. Although moderately free from evidence of inflammatory action in front, the retina seemed to be involved in a dense mass of exudation behind, passing as it did into a thick column which passed backwards to the entrance of the optic nerve and spread out all round on to the choroid. The ectasia was found to be a dilatation of an infiltrated and thickened sclerotic. There was a mass of tissue joined to the base of the before-mentioned column and to the choroid to the inner and upper side of the entrance of the optic nerve, which mass appeared to be of a different consistence from the rest of the column, presenting signs of degeneration. The choroid was altered in the ectasia but not thickened, whilst over the rest of the globe it was much thickened. There was no evidence of external propagation of the growth.

Microscopic examination.—The microscopic examination of the anterior part of the eyeball calls for no special comment here. It will be sufficient to say that there was a general and simple inflammation of the iris and ciliary body but no evidence of special inflammatory process. The posterior part of the column which passed from the sclera to the lens was found to be composed of densely packed round cells with recognisable remains of retinal structure and in a few places formations typical of tubercle. The same round-cell exudation with tuberculous characteristics was found in the thickened choroid, and the degenerated mass, which measured eight millimetres across, was found to be composed of much the same structure, only that in several parts the cells were so far degenerated that they would not stain, their outlines being utterly destroyed. The giant cells which in almost every instance were found in the centre of the tuberculous structures were of large size and had their nuclei arranged round the periphery. Special staining failed to bring out tubercle bacilli.

Remarks by MR. EDINGTON.—The above case has appeared to me to be of sufficient interest to be recorded on account of the question which it raises of dissemination as a result of partial operation for tuberculous disease. The remarks which I have to make on the case may very properly be preceded by a short mention of the views on choroidal tuberculosis of some of the writers on diseases of the eye. Macnamara and Hartridge[2] mention tuberculosis of the choroid as occurring in two forms: (1) chronic choroiditis, which may be primary or associated with tuberculosis of the brain—as a rule this form is insidious in its progress and unilateral in its distribution; and (2) miliary tubercle, which is much more common and usually part of a general tuberculosis. It affects both eyes commonly and the tubercles are numerous. Sometimes the condition is only seen in the advanced stage of a tuberculosis and at first causes but little pain or discomfort. Berry[3] describes the following forms: (1) miliary which is acute and always secondary to tuberculosis in other organs, is generally bilateral, probably never accompanies pulmonary tuberculosis alone, and appears to have no definite relation to tuberculous meningitis; and (2) *chronic* tuberculous choroiditis which is much rarer, unilateral, and sooner or later associated with similar diseases of the brain ending fatally. Panas[4] also speaks of: (1) miliary or disseminated, almost always accompanying meningeal tuberculosis and appearing in the posterior part of the choroid; and (2) circumscribed, in the ciliary region, usually associated with pulmonary phthisis, but may be primary. At first there is scarcely a perceptible reaction and in a child with meningitis it is often overlooked. If it reaches the ciliary region tuberculosis of the choroid may resemble panophthalmitis, and in children this acute variety is more common. Noyes[5] declares that choroidal tubercle occurs most commonly in tuberculous meningitis and general miliary tuberculosis, but he mentions a case recorded by Fraenkel in which the choroidal condition preceded all the symptoms of general tuberculous deposit by six months. Berry[6] quotes Horner's view that the choroid acts as a substitute for pia mater and that choroidal tubercle occurs least commonly in children in whom meningitis is likely. It will be seen from the above that although tuberculosis of the choroid may occur primarily and alone, yet it is most often the accompaniment of tuberculous lesions elsewhere. It may exist imperceptibly for a time and then takes on the character of an acute irido-cyclitis. Opinions differ as to its accompanying or replacing tuberculous meningitis. The chronic form tends to be unilateral and the acute form to affect both eyes. In connexion with the question of syphilis which entered into the diagnosis von Arlt[7] may be mentioned who, speaking of scrofulous iritis, states that he has seen undoubted cases of scrofula which could be attributed to no other cause than hereditary syphilis. While Panas mentions the acute termination to choroidal tubercle, especially in children, yet this event, taking place so very shortly (four days) after an incomplete operation on the limb, must raise the question either of a dissemination or a stirring-up of a quiescent lesion. Watson Cheyne[8] instances scraping as likely to cause dissemination of tuberculosis, but it is more likely that the choroidal lesion was not a fresh one but a chronic condition stirred up. The unilateral distribution of the lesions was a curious feature in this case, but Dr. Gibb of Paisley, under whose care the patient now is in the infirmary there, informs me that he recently excised the boy's left elbow at the same time observing that the right showed signs of tuberculous disease.

PATHOLOGICAL SOCIETY OF LONDON.

Congenital Hypertrophy of the Pylorus.—The "Buffy Coat."—Alveolar Sarcoma of the Rectum.—Dilatation of the Œsophagus.—Colloid Carcinoma of the Stomach.—Papillomatous Tumour of the Umbilicus.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 7th, Dr. RADCLIFFE CROCKER, Vice-President, being in the chair.

The VICE-PRESIDENT referred with much regret to the death of Professor Coats of Glasgow and the society directed that a letter of sympathy should be sent to Mrs. Coats.

Dr. STILL reported three cases of Congenital Hypertrophy of the Pylorus. The first case was that of a boy, aged 12½ weeks at death, in whom vomiting began at the end of the sixth week (some previous regurgitation of food had been thought natural by the mother). The vomiting persisted and increased until death; the thickened pylorus was distinctly felt shortly before death. The necropsy showed great hypertrophy of the stomach and pylorus, the latter being normally patent. The second case was that of a boy, aged 15 weeks at death. Vomiting began at six weeks of age and increased until death, with constipation and subnormal temperature. Marked peristalsis of the stomach appeared and the thickened pylorus was distinctly felt the day before death. At the necropsy the stomach was found to be dilated and hypertrophied; the pylorus especially was greatly thickened; its lumen was normally patent. The third case was that of a boy, aged 15 weeks at death, in whom regurgitation of food began at seven days. The bowels were costive and vomiting increased. Marked peristalsis of the stomach appeared and the thickened pylorus could be felt distinctly about a fortnight before death. The necropsy showed great hypertrophy of the stomach and pylorus and some also of the œsophagus. The lumen of the pylorus was normally patent. In all these cases the thickening was almost entirely muscular and chiefly in the circular layer. In Case 3 the submucosa also was abnormally thick. Dr. Still in discussing the pathology of this condition thought that a fuller study of the normal pylorus at this age was much needed. He had made some observations from which it was evident that there was considerable variation in the thickness of the normal pylorus in infancy and that this variation was chiefly in the circular layer of the muscular coat. Further, it would appear that the lumen of the normal pylorus as measured post mortem was often not more than from 3 5 to 4 mm. Much caution therefore was necessary in judging a slight degree of hypertrophy and it was evident that the lumen in many, at least, of the cases of congenital hypertrophy of the pylorus was within the normal limits when muscular contraction was absent. Four views had been propounded of the pathology of this condition: (1) that it was entirely extra-uterine and due to spasm from some irritant; (2) that it was due to a developmental hyperplasia; (3) that a primary congenital stenosis was followed by compensatory hypertrophy; and (4) that the hypertrophy was due to over-action from a functional disorder of the nervous mechanism in utero. Dr. Still thought that in considering the pathology of this condition there were two facts in particular which could not be overlooked—the occasional occurrence of an "idiopathic hypertrophic stenosis of the pylorus" in adults and the increasing evidence that some of the cases of congenital hypertrophy of the pylorus recovered. On the whole, it seemed most probable that the condition was intra-uterine in its origin, but the cause must be a potentially transient one and therefore a functional disturbance seemed more in accordance with the facts than a vice of developmental growth. There were moreover cases which seemed to support this view by analogy, particularly cases in which the œsophagus was found to be hypertrophied without any demonstrable cause.

Dr. E. CAUTLEY showed three specimens of the same condition from infants aged respectively 15, eight, and seven weeks. Vomiting had been almost constant since they were three weeks old. In none was any etiological factor discoverable. Dr. Cautley held that this was a pre-natal condition and that the hypertrophy took place in the circular muscular fibres. The stenosis was largely due to plication of the mucous membrane by the muscular spasm. He thought that hyperplasia of the muscular fibre took place in the fœtus.—Dr. ROLLESTON showed a similar specimen taken from a child who died when eight weeks old. He agreed that the hypertrophy was probably due to spasm. Metzler, however, had doubted whether spasm had ever been shown to cause hypertrophy in the case of unstriped muscle and he asked for an expression on that point.—Dr. F. E. BATTEN said that he had recently had what appeared to be a case of this kind under his care. The pylorus was palpable and there was continuous vomiting and constipation. The child was fed by a nasal tube, as recommended by Dr. John Thomson, and the vomiting ceased; before the child left hospital it had been fed by the mouth without serious vomiting for two weeks. This improvement, however was not kept up and a week ago the mother reported that the vomiting had returned.

Mr. S. G. SHATTOCK submitted a new interpretation of the phenomenon known as the "Buffy Coat" which he illustrated by microscopic and other preparations, maintaining that the principal factor was rapid clumping of the red corpuscles and not, as commonly taught, simple retardation in coagulation. He believed that this clumping was due to some agglutinating substance which varied in amount in different animals. In the cat it was scanty, and if cat's blood was received into an equal quantity of salt solution and clotting deferred by keeping in ice no well-formed buffy coat resulted. If, on the other hand, the cat's blood was received into an equal quantity of horse's blood which was rich in agglutinating substance, subsidence of the clumped red cells quickly commenced and a well-formed buffy coat resulted if the tube were kept in ice. A similar effect was observed if horse's serum were mixed with human blood. But the most striking clumping was seen when serum from the blood of a patient suffering from pneumonia was added to a hanging drop of human blood. (A specimen was shown.) He regarded the agglutination of the red discs as due to the same substance which clumped the diplococci of pneumonia in living cultures and therefore was a form of Durham's, or more correctly of Widal's, reaction, since it was obtainable during the stage of infection.—Mr. D'ARCY POWER observed that Mr. Shattock's observations tended to reinstate the older physicians who were accustomed in pneumonia to bleed repeatedly until the blood no longer gave a buffy coat.

Mr. STANLEY BOYD showed Microscopic Sections of a New Growth of the Rectum which had the clinical characters of a columnar epithelioma but which histologically seemed to be an alveolar sarcoma. The patient was a woman, 35 years of age. Almost every one of the large cells of which the growth consisted seemed to be in a separate space in the delicate fibrous stroma. The case was interesting also because the cæcum perforated on the third day after colotomy had been performed and obstruction was freely relieved. She lived 30 days after the perforation, suffering chiefly from dyspnœa due to distension of the abdomen by intestinal gases. Post mortem the gas was found to be contained in a huge cavity in which no viscera were visible. They lay behind a thick layer of lymph and though compressed were healthy. There were no signs of peritonitis behind the layer of lymph. The tumour was referred to the Morbid Growths Committee.

Dr. LAZARUS-BARLOW showed a Dilated Œsophagus of a man, aged 28 years. It was the seat of a fusiform dilatation which at its greatest circumference measured three and a half inches. The history was indefinite, but it appeared certain that difficulty of swallowing and frequent vomiting which had led to the surgical passage of œsophageal bougies had existed for at least a year. The chief symptoms were immediate regurgitation of food upon its ingestion and extreme emaciation. Laparotomy was performed upon the suspicion that there was disease of the stomach, but nothing abnormal was found in the stomach or elsewhere. The patient died on the ninth day after admission and the third after laparotomy from asthenia. At the necropsy general miliary tuberculosis was found, but it was not extensive and was chiefly confined to the upper lobe of the left lung. It could only be regarded as an adjuvant cause of death. The muscle of the œsophagus was greatly hypertrophied and had undergone no change that might not fairly be ascribed to post-mortem decomposition. Since it had been recently shown by Langley that the vagus contained fibres which on stimulation lead to dilatation of the lower end of the œsophagus the vagus was examined in this case by Dr. S. F. Grünbaum, but sections presented no definite evidence of either recent or former degeneration of the nerve.—Dr. **ROLLESTON** showed, for Dr. **WARDROP GRIFFITH**, a similar specimen. Dr. Rolleston thought that the cases were best explained not on the supposition of the existence of a "cardiospasm" but of defective action of the longitudinal fibres of the œsophagus so that the cardiac orifice did not open. Dr. Griffith had suggested that the atonic œsophagus might be further dilated through the negative pressure in the thorax.—Dr. **STCLAIR THOMSON** mentioned the case of a patient who had suffered for many months from Dysphagia and Vomiting supposed to be due to Malignant Disease. He believed that the œsophagus was dilated in this patient and as one vocal cord was paralysed from implication of laryngeal nerves he thought that similar involvement of the vagus might be the cause of the dilatation of the œsophagus. He asked Dr. Lazarus-Barlow whether he had examined the nerves at the base of the skull in his case.—Dr. **PARKES WEBER** also asked for information as to the condition of the brain, observing that symptoms of stricture of the cardiac orifice might be produced by chronic internal hydrocephalus in the adult.—Dr. **LAZARUS-BARLOW** said that he had not examined the brain.

---

[8] Tuberculous Disease of Bones and Joints, p. 168, Edinburgh, 1896.

Dr. **R. G. HEBB** showed a specimen of Colloid Cancer of the Stomach from a woman, aged 36 years, who had had pain and vomiting for some months before death. No tumour could be felt during life. The œsophagus was found to be hypertrophied and slightly dilated and there were many corn-like elevations in the walls. The walls of the stomach were infiltrated with colloid cancer and the pyloric half was ulcerated. There was enlargement of the glands just below the diaphragm. On section they contained large spherical carcinomatous cells, but there was no colloid degeneration.—Dr. **LAZARUS-BARLOW** asked whether the "corns" on the œsophageal lining were looked on as malignant and as indicating an extension along the course of the lymphatics.—Dr. **HEBB**, in reply, said that he had not examined the elevations microscopically, but he regarded them as simple thickenings and not malignant.

Dr. **C. D. GREEN** showed a Papillomatous Tumour of the Umbilicus which he had removed by operation from a woman 50 years of age. The macroscopical characters of the specimen were simply those of an ordinary cutaneous papilloma but the histological examination showed the presence of gland structures and of unstriped muscular tissue. The majority of the gland structures were lined with long columnar epithelium with large deeply staining nuclei situated quite near the basement membrane and were considered to be reproductions of the intestinal glands known as Lieberkühn's crypts, differing from the normal intestinal structures in their exaggerated dimensions and in the absence of any definite arrangement. The surface of the tumour was covered with stratified epithelium of the cutaneous type, the superficial layers of which had undergone keratinisation, and this superficial epithelium sent processes into the deeper parts giving rise to a papilliform appearance. No cutaneous gland structures were seen. Dr. Green considered that the tumour was derived from the remains of the vitello-intestinal tract, but that it differed from other published cases of the same nature in being covered with epithelium of the cutaneous type and as regarded the age of the patient. The specimen was referred to the Morbid Growths Committee.

The following card specimens were shown:—

Dr. **CAUTLEY**, Dr. **MORLEY FLETCHER**, and Dr. **ROLLESTON**: Specimens of Congenital Hypertrophy of the Pylorus.

Dr. **LEONARD GUTHRIE**: A specimen of Meckel's Diverticulum forming part of an Umbilical Hernia.

Dr. **H. B. HICKMAN**, Dr. **A. F. VOELCKER**, and Dr. **PARKES WEBER**: Specimens of Carcinoma of the Stomach.

OBSTETRICAL SOCIETY OF LONDON.

Annual Meeting.—President's Address.—Appointment of Officers.—Exhibition of Specimen.

THE annual meeting of this society was held at 20, Hanover-square, W., on Feb. 1st, Dr. **C. J. CULLINGWORTH**, President, being in the chair.

The reports of the treasurer, honorary librarian, and chairman of the Board for the Examination of Midwives having been read, received, and adopted the retiring President, Dr. **CULLINGWORTH**, delivered his Annual Address. He said that although the work of the secretaries in that society was by no means a sinecure and was, indeed, heavier and more exacting than anyone not intimately acquainted with the official nature of the society would suppose, there was one duty from which they were exonerated—namely, the preparation of an annual report. It had always been usual in that society for the President at the close of his year of office to give an account of the condition of the society and of the work done during the year. Following this long-established custom he had to begin by deploring a further slight falling off in the number of Fellows. The total number of Fellows on the roll on Jan. 1st, 1898, was 711, comprising 11 honorary and corresponding Fellows and 700 ordinary Fellows. During the year the society had lost 12 Fellows by death (including a death which occurred in 1897 and had been accidentally overlooked) and 30 by resignation. 22 new Fellows had been elected. Hence the number on the roll had been reduced by 19. The present total (Jan. 1st, 1899) was 692, of which number 10 were honorary and corresponding Fellows and 682 ordinary Fellows. This diminution in numbers ought not to be and would not be if only each one would bestir himself in the way of beating up recruits. During the past year the Council, acting in conjunction with the Board for the Examination of Midwives, had drawn up a code of rules and regulations to be observed by midwives holding the society's certificate. These rules had now been printed and circulated and a copy would be supplied to every Fellow of the society in the form of an appendix to the forthcoming volume of Transactions. He (the President) regarded the preparation and issue of these long-wanted rules as quite the most important event which had happened in the society during his term of office. In the matter of its examination for midwives the society continued to suffer from a certain amount of professional opprobrium which, though entirely undeserved, was probably in some degree responsible for the decrease in their numbers. He wished once more to remind their professional brethren that the society undertook the work from a sense of public duty and merely as a temporary expedient after having tried in vain to induce the Government to move in the matter; he assured them that it would be only too glad to relinquish it whenever the State could be prevailed upon to take upon itself functions which properly belonged to it and which it alone could adequately fulfil. The President proceeded to review the scientific work of the society during the past year, giving a brief abstract of each of the papers read, 15 in number (10 obstetrical and five gynæcological), and classifying the specimens shown in groups according to the particular subject which it was the intention of the exhibitor to illustrate. The names of the deceased Fellows were then announced, each announcement being followed by an obituary notice. The first and longest notice had reference to the late Dr. Charles West, an honorary Fellow and Past-President of the society, and the other names mentioned included those of Dr. Karl Liebman of Trieste, Dr. Leonard Remfry, Brigade-Surgeon Joseph Johnston, Mr. E. Arnold Praeger of California, Deputy-Surgeon-General John R. Miller Lewis, M.D. Glasg., Dr. George Roper, Dr. John Wallace of Liverpool, Dr. W. F. Cleveland, Dr. C. E. Fitz-gerald of Folkestone, Mr. Alfred Kebbell of Flaxton, York, and Professor A. A. Kanthack of Cambridge. The address concluded with a word of farewell and of thanks to the Fellows and especially to the President's colleagues in office for the help and support uniformly accorded to him in the conduct of the society's business both in the general meetings and in the council room In resigning this chair, said Dr Cullingworth "it is a satisfaction to me to know that its next occupant is to be one of whose contributions to scientific gynæcology all British gynæcologists are justly proud and whose irrepressible but never unkindly humour may be relied upon to relieve the dulness of even your very driest debates I congratulate you and I congratulate him The best I can wish him is that his tenure of this high office may be as pleasant and as peaceful as mine has been

The following officers and members of council were appointed for the year 1899 —President Mr Alban Doran Vice Presidents Dr John W Byers (Belfast) Dr William Radford Dakin Dr William Duncan and Dr Jamieson Boyd Hurry (Reading) Treasurer Dr James Watt Black Chairman of the Board for the Examination of Midwives Dr Percy Boulton Honorary secretaries Dr John Phillips and Dr Herbert R Spencer Honorary librarian Dr Amand Routh Other members of the Council Dr Augustus W Addinsell Dr John Ford Anderson Dr A H Freeland Barbour (Edinburgh) Dr George Francis Blacker Dr Robert Boxall, Dr Thomas Watts Eden Dr Angus Fraser Dr Arthur Edward Giles Dr Thomas Crawford Hayes Dr Ernest Herman Dr John Dysart McCaw, Dr Arthur Nicholson (Brighton) Mr Richard Pinhorn (Dover) Dr William Loudon Reid (Glasgow) Dr Charles Hubert Roberts Dr George H Drummond Robinson Dr William Japp Sinclair (Manchester) and Dr Arthur Francis Stabb

On the nomination of the council the following distinguished persons were unanimously elected to the honorary Fellowship of the society—viz Professor Olshausen of Berlin Dr Budin and Dr Pinard of Paris Dr A F Martin of Berlin Dr H Oldham of Bournemouth (an original Fellow and Past President of the society) and Mr Hutchinson of London

Certain proposed alterations in the laws were then confirmed and the meeting concluded with votes of thanks to the retiring President Vice-President, and members of council

A specimen of Tubo Ovarian Abscess was shown by Dr CULLINGWORTH at the commencement of the meeting

HARVEIAN SOCIETY OF LONDON

Hygroma of the Neck —Congenital Deformities of Limbs —Mumps —Middle ear Disease

A CLINICAL meeting of this society was held on Feb 2nd the President Mr HENRY JULER being in the chair

Mr RAYMOND JOHNSON showed a girl aged eight years who was the subject of a large congenital Cystic Hygroma of the Neck She had been under observation since the age of 16 months and the tumour had progressively but slowly diminished in size On three occasions the tumour had been the seat of attacks of violent acute inflammation during which the swelling became enormously increased in size and there was rather severe constitutional disturbance On each occasion the inflammation subsided spontaneously and was followed by a more rapid shrinking of the tumour One of the largest cysts had been treated by drainage but in view of the very marked tendency of the tumour to shrink and its extent and diffuse character it was not proposed to make any attempt to remove it by operation —Mr D'ARCY POWER said that such growths when they occurred in the neck seemed always to involve the lobule of the ear as the early photographs showed had been the case in this child At the present time however the lobule of the ear was separated from the growth by a considerable distance Mr Power alluded to four other cases of a similar kind in the same situation upon which he had lately operated He had been able to remove the bulk of the growth in three of the cases but in the fourth it was so extensive and it involved such important structures that much had to be left behind Yet in this case the remainder of the growth absolutely vanished in the course of a few months and after attacks of lymphangitis like those described by Mr Johnson Mr Power stated in reply to a question by Dr Joll that these tumours were known to the older pathologists as hygromata or barren cysts Hygroma from the Greek ὑγρὸς because they were supple and barren because having only an endothelial lining they did not proliferate

Mr JACKSON CLARKE showed a girl aged three years who had several Congenital Deformities When he first saw the patient at the age of six months the thumbs were firmly adducted into the palms and the forearms were abnormally curved with a forward concavity There was also marked double equino varus About the middle of the forearms and legs there were depressed scar like marks one over the middle of each of the bones on the extensor aspect In the legs a small nodule of bone could be felt beneath each of the marks The mother said that the birth was 'very dry' Mr Clarke thought that the abnormalities were explained by a deficiency of liquor amnii allowing of abnormal intra uterine pressure upon the fœtus The deformities of the hands and feet completely recovered under gradual *methods* Mr Clarke wished to express his preference for such methods over procedures such as Phelps's operation which in his opinion was undesirable as applied to club foot in children —Mr D'ARCY POWER asked Mr Jackson Clarke whether he had been able to elicit any history of syphilis in this case or whether there was any evidence of placental inflammation He thought that the dimpling had been caused by the presence of allantoic bands for it was so exactly symmetrical The irritation of the bands had led to the slight hypertrophy of the bone underlying each dimple —Mr JACKSON CLARKE replied that he had not been able to obtain any evidence of syphilis in his case and in answer to a question by Mr Johnson he stated that the feet had been treated with the splint which he usually employed in such cases—a strip of tinned iron applied to the outer side of the leg and foot and gradually bent so as to overcome the deformity

Dr EWART showed a case of Mumps with Marked Enlargement of the Spleen The patient a boy aged 13 years was admitted into hospital on the third day of the attack with a characteristic swelling of the left parotid The affection remained limited to the left side and ran a mild course without pyrexia The only complication was an enlargement of the spleen which persisted for several days and gradually subsided as the parotid gland returned to its normal size Dr Ewart had not found in text-books any reference to this complication which may perhaps sometimes occur unnoticed In this case it gave rise to no symptoms The dulness measured six and a half inches in the horizontal and five inches in the vertical direction The enlargement took place upwards the spleen projecting half an inch only below the costal arch The spleen when percussed at the meeting was of normal size and yielded the 'bony' percussion note which as recently pointed out sometimes replaces the splenic dulness A specimen of the blood had been stained for micro organisms by Mr Hunt with negative results —Dr C O FOWLER and Dr MAGUIRE discussed the case and Dr EWART replied

Dr G WILLIAM HILL showed a young woman who had been the subject of Chronic Suppuration in the Middle Ear and who for two years had suffered from Facial Paralysis associated with Paralysis of the corresponding half of the Soft Palate No evidence of diphtheria was obtainable The interest of the case consisted chiefly in its bearing upon the question as to whether or not the muscles of the palate received any part of their nervous supply from the facial —Dr HERBERT TILLEY said that if the case was one of combined facial and unilateral palatal paralysis it would seem to point to the fact that the palate may have a double nerve supply the facial through the Vidian and the spinal accessory by the pharyngeal branches of the vagus That the latter innervation is the most constant (and probably the sole one) had been experimentally proved beyond any doubt by Horsley and Beevor in monkeys whilst clinical evidence was almost altogether in favour of the view He then referred to three cases of the kind which had recently come under his notice

Dr EWART and Mr E L HUNT described a case of Diphtheritic Membranous Tracheitis with temporary obstruction of the right bronchus in the adult and exhibited a series of tubular casts of the trachea expectorated on the third fourth and fifth days of the attack by a woman aged 32 years who was now recovering after a pyrexial period of 19 days from a severe pulmonary catarrh due as shown by repeated cultivation to diphtheria She had been injected on the third and on the fifth days with 4000 units of antitoxin On the third day the laryngoscope had shown the presence of membrane immediately above the glottis For several days there was loss of respiratory sounds and diminution of right respiratory movements With the return of the respiratory function abundant râles developed The patient was aphonic for 15 days; but the cough was not "croupy" and there was no stridor or spasm of the glottis. An alarming attack of heart failure had occurred on the tenth day, but neither albuminuric nor paralytic symptoms have made their appearance.—Mr. E. L. **HUNT** gave details of the administration of the antitoxin.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Cubitus Varus following Fracture of the Lower End of the Humerus.—Charcot's Joint Disease.—Tuberculosis of the Liver.—Ulceration of the Cæcum.—Exhibition of Card Specimens.

A MEETING of this society was held on Jan. 18th, Dr. R. B. **WILD**, President, being in the chair.

Mr. J. E. **PLATT** discussed the Pathology of Cubitus Varus following Fracture of the Lower End of the Humerus and illustrated his remarks by a number of skiagrams. After briefly referring to the various kinds of fracture which may occur in the lower end of the humerus he said that cubitus varus had been met with as a result of the following injuries: (1) oblique fracture of the external condyle extending into the elbow-joint, with permanent displacement downwards of the loose piece of bone; (2) oblique fracture of the internal condyle with displacement upwards of the loose fragment; (3) transverse supra-condylar fracture with tilting of the fragment, so that the trochlea lay at a higher level than the capitellum; and (4) separation of the epiphysis. It was stated that when cubitus varus followed separation of the epiphysis its pathology was more complicated and that the deformity might be produced in at least three different ways: (1) from the line of fracture in these cases being usually partly epiphyseal and partly diaphyseal, with frequently some inward displacement of the fragment (imperfect reduction under such circumstances would be very liable to lead to cubitus varus); (2) from rotation of the epiphysis around the convex end of the diaphysis; and (3) from irregular growth at the epiphyseal line after the union of the fracture. It had been found as a result of the examination of a number of cases of epiphyseal separation some years after the injury that in two patients cubitus varus had gradually supervened although the fracture had united without deformity in the first instance. This was attributed to the epiphyseal cartilage having been permanently damaged by the accident.

Mr. **SOUTHAM** showed two specimens of Charcot's Disease of the Ankle-joint removed by amputation below the knee from male patients, aged respectively 44 and 49 years, the subjects of locomotor ataxy. In both cases extensive erosion of the articular surfaces had taken place in consequence of which the foot had become dislocated upwards and outwards and in one instance the internal malleolus had projected through the skin.

Dr. F. C. **MOORE** described the morbid features of two uncommon forms of Hepatic Tuberculosis and exhibited the specimens. The first, an example of the so-called "large solitary tubercle," was found in a male, aged 43 years, in association with a similar lesion in the spleen, tuberculosis of the aortic lymphatic glands, and a typical carcinomatous stenosis of the pylorus. The other organs were healthy. The second, an example of tuberculous hepatitis, was met with in a rabbit which had been inoculated 12 months previously with a few highly virulent tubercle bacilli. The interstitial changes consisted in an increased formation of fibro-cellular tissue, monolobular in distribution, which showed no tendency to tubercle formation. Psorosperms were absent. The lungs were the seat of extensive tuberculosis.

Dr. **MARSDEN** showed a preparation from a case of Ulceration of the Cæcum.

The following card specimens were exhibited:—

Dr. T. A. **HELME**: Gynæcological Specimens.

Mr. **HITCHON**: Chronic Gastric Ulcer.

Dr. **LEA**: A series of Uteri removed by Vaginal Extirpation.

Dr. **MOORE**: Psammoma

Mr. **SOUTHAM**: Tuberculous Mesenteric Gland sloughing into the Intestine.

Dr. **WALLS** Fœtus Papyraceus

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Treatment of Ozæna.—Moveable Kidney.

THE fifth ordinary meeting of this society was held on Feb. 1st, Sir JOHN BATTY **TUKE**, President, being in the chair.

Dr. ROBERT **FLEMING** showed a family consisting of the mother and four children all apparently suffering from Addison's Disease. With reference to the mother it was stated that after each successive pregnancy her skin became darker, but this disappeared to a great extent until after her last pregnancy which occurred two years ago. Since then she had complained of ill-health; her skin was dark in colour and this darkening was noticed to be more marked in summer than in winter. There were no dark markings on the buccal mucous membrane, but many black spots (moles) had appeared recently on the skin of the face, arms, and body. She suffered from vomiting and diarrhœa, faintness, and extreme languor. The four children also presented the same combination of symptoms. The eldest, a girl, aged seven years, who began to become pigmented four years ago, was fair at birth but was now dark and had a large number of moles. The next child was also a girl, aged four years, and presented exactly the same appearances, as did also a boy, aged three years. The youngest, aged two years, had been noticed to be darker and several moles had recently appeared. The cases had not been treated with suprarenal extract, but were apparently benefited by taking arsenic and other remedies.

Dr. WILLIAM **RUSSELL** and Mr. **COTTERILL** showed a boy after operation for Mastoid Abscess and Empyema. The lad was seen in consultation on Nov. 27th, 28th, and 29th, 1898, but had been ill for more than a week previously. He had severe rigors for two days and on examination pleural friction on the left side was evident. On the 28th the friction had disappeared and there was no effusion, but rigors continued, and it was not until the 29th that he complained of pain in the left ear and there was swelling and tenderness over the mastoid and it became evident that the rigors were due to mastoid disease. Four days later he was admitted to the infirmary under the care of Mr. Cotterill. The point of interest was that the rigors continued without any ear symptoms showing themselves for several days. The pulse was never above 60 and this slowing was probably due to compression of the brain, as after the operation and the evacuation of intradural pus the pulse regained its normal frequency. Some days after the ear operation pus was evacuated from the right pleura. Mr. Cotterill remarked that there were many signs of phlebitis of the lateral sinus, as swelling and tenderness low down in the neck. These signs were absent in this case. On operation the mastoid antrum was found to be comparatively healthy, there being only a little inspissated pus present. The abscess extended backwards towards the cerebellum and downwards through the jugular foramen.

Dr. **SHENNAN** showed microscopic preparations of (*a*) the Vessels from a case of Tuberculous Meningitis; (*b*) Section through the Glans Penis with early Tubercle (giant cells) under the Urethral Mucous Membrane; (*c*) ordinary long form of the Diphtheritic Bacillus; and (*d*) Organism from Cancrum Oris. This was separated 24 hours post mortem. It somewhat resembled the diphtheria bacillus and Kanthack said that it was allied to it or was a debased form. It appeared like an involuted form of Löffler's bacillus with clubbed ends. A pure cultivation of the diphtheritic bacillus was obtained from the same case during operation. From a case of acute spreading gangrene a similar culture to the present was obtained.

Dr. ROBERT **FLEMING** exhibited two Mammillated Stomachs. One was obtained from the body of a woman, aged 54 years, who died apparently from excessive vomiting. There were curious little projections over the whole of the mucous surface. The second was from a case of chronic gastric catarrh due to heart disease. Another specimen showed a chronic gastric ulcer which was adherent to, and had penetrated into, the liver. Dr. Fleming also showed a Heart with Aneurysm of one of the Sinuses of Valsalva.

Dr. WILLIAM **STEWART** and Dr. JOHN **THOMSON** exhibited a specimen of Congenital Malformation of the Œsophagus. The child seemed able at first to swallow small quantities of milk-and-water. Later all was returned. On passing a bougie down the gullet it stuck at a point about three inches. Gastrostomy was performed but the infant died. The specimen showed that the upper end of the œsophagus ended blindly in a test-tube-like manner about an inch from its commencement, while the upper end of the lower portion opened directly into the trachea.

Mr. **COTTERILL** showed part of the Large Intestine, showing the Line of Suture (almost invisible) after Enterectomy performed 11 years previously for a gangrenous umbilical hernia; 22 inches of the bowel were removed at that time.

Dr. **PETER McBRIDE** read a paper on the Treatment of Ozæna, with Special Reference to Cupric Electrolysis. He drew attention to the characteristic atrophy of the nasal mucous membrane in such cases, the change of the ciliated epithelium into the flat form, and to the drying and extreme fœtor of the secretion. As a rule no ulceration could be detected; the atrophy chiefly affected the inferior turbinated bone. Numerous organisms were present in the nose and a modified form of Loffler's bacillus was found. The disease usually began about puberty and was considered as an almost incurable malady. The therapeutic principles which had been in use were chiefly (1) the destruction of the secreting membrane, as by curetting, &c. 2. The application of stimulating and irritating remedies; palliatives had perhaps been most efficacious. The electro-cautery had been used as well as "vibratory massage," carried out by means of a probe armed with wool which when introduced into the affected parts of the nares was rapidly made to vibrate either by the hand or by an electric motor. This latter treatment had, however, in some cases produced hypertrophy of the mucous lining. 3. Widening of the nasal chambers by means of obturators, &c., in order to favour expulsion. Sprays of ichthyol and glycerine or other antiseptics were satisfactory. The injection of diphtheritic antitoxin had been employed because of the presence of the organism which resembled Löffler's. One observer stated that by this treatment he had cured 16 cases out of 32. Dr. McBride then described the mode of treatment by cupric electrolysis and related a number of cases treated thus by himself. Of eight unselected cases (two males and six females) four were practically cured. At least, they remained so for long periods—18 months. The others had been treated at so recent a period that it was impossible to say whether they were permanently cured. The current used varied from three to 10 milliampères. Cocaine was used as an anæsthetic. The copper needle was attached to the positive pole and was inserted into the inferior or middle turbinated bone, while the platinum or steel needle was inserted into the septum. There was little or no pain either at the time or subsequently. The beneficial effects might be as largely due to the copper salts produced as to the electricity. If the cases relapsed the treatment required to be repeated perhaps twice yearly, but at any rate it seemed to be a valuable therapeutic remedy for a most obstinate disease.—Dr. **LOGAN TURNER** remarked that the interest in the treatment lay in the possible *rationale*. Even after cupric electrolysis the same organisms were found in the nose as before; the treatment was therefore not bactericidal and the good effects were seen in both nostrils though the application was made to one alone. It must rather be a trophic action and the serum treatment might act in a similar manner by causing a general stimulation and a consequent throwing off of the crusts.—Dr. **GEORGE HUNTER** drew attention to the good effects produced by applying blistering fluid to the atrophic areas.—After some remarks by Dr. **SHENNAN** Dr. **McBRIDE** replied.

Dr. **DAVID WALLACE** read a paper on Moveable Kidney. After briefly sketching the history of this affection as recorded by various writers he noted that it occurred more frequently in females than in males and that the right kidney was more often free than the left. Formerly it was said to be a commoner affection amongst the poor than amongst the rich. This assertion was controverted by Greig Smith who stated that tennis, riding, &c., were as frequent causes amongst the well-to-do as over-frequent pregnancies and curtailment of rest amongst the poor. The experience of Dr. Wallace went to prove that statement. He thought that a loss of fat predisposed to the condition. On the other hand, however, it might only render the moveable kidney more easy of palpation. Was emaciation really the cause or the effect? He referred to the recent anatomical descriptions of the kidney surfaces and pointed out how a variation in its normal anatomical relationship was the probable cause of the condition. Dr. Wallace thought that the ordinary degree of mobility of the kidney was its safeguard and that when it was too tightly fixed then there was a greater likelihood of its becoming free. As a rule detection of the condition was not difficult. The moveable kidney was thought to be larger than normal merely from its free movement under the fingers. The usual symptoms of this affection were—(1) mobility of the organ itself; (2) pain of a dragging or aching character; (3) renal pain was distinctive; there might be hæmaturia or intermittent hydro nephrosis; and (4) gastro-intestinal derangements which might end in neurasthenia. These gastric symptoms were due probably to a dragging down of the duodenum. The moveable kidney was usually quite normal, though in some cases it was the seat of a calculus. The symptoms usually entirely disappeared on fixing the organ in its normal position. Intermittent hydro-nephrosis was an infrequent symptom. If the tumour be present it might hide the condition as the kidney might appear to be fixed. As regards treatment there were three classes of cases. 1. Those where no treatment was necessary. In such cases nothing should be said to the patient regarding the condition which was usually made out while examining for some other disease. 2. Those benefited by wearing a pad. 3. Those where operation was necessitated. Of 14 cases treated by Dr. Wallace one occurred in a male as a result of a fall from a horse and was treated by operation, while 13 were in females. Two cases were of the gastro-intestinal type and were successfully treated by the wearing of a distensible air-pad which was fixed over the region of the kidney to the inner side of the corset. Such a pad was much more useful than the solid forms fixed to belts. The method of operation carried out in several of the others was that of separating the perirenal fat and cutting it off, then three or more deep catgut sutures were introduced through the cortex, and the kidney was fixed as high up as possible to the abdominal wall.—Mr. **COTTERILL** remarked that his worst cases had occurred in multiparæ and that the amount of displacement bore no relation to the severity of the symptoms. He described the method by which he fixed the kidney, transfixing the posterior abdominal wall and bringing both ends of the silkworm ligature to the skin surface and tying them together.—Dr. **WILLIAM RUSSELL** remarked that many of the women inmates of Queensberry House had moveable kidney. In making post-mortem examinations he found the kidney freely moveable under the peritoneum as far as the spine or brim of the pelvis. He could not see that the moveable kidney had any connexion with the duodenum so as to produce symptoms of stricture and related the case of a woman who suffered from prolapse of all her abdominal organs, the pylorus being at the level of the umbilicus, and yet there was no effect produced on it by the freely moveable kidney.—After other remarks by Dr. **STILES**, Dr. **LUNDIE**, and Dr. **CHURCH**, Dr. **WALLACE** replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Juvenile Muscular Atrophy.—Beri-beri.

A MEETING of this section was held on Jan. 27th, Dr. J. W. **MOORE**, the President, being in the chair

Mr. **LANGFORD SYMES** exhibited a case of Erb's Juvenile Muscular Atrophy. The patient was a boy, aged eight and a half years. He had been ailing since he was two years old, when he was learning to walk. If he fell he could not get up alone. He was now becoming more helpless, could not walk up stairs, and was unable to get in or out of bed.

Mr. **CONOLLY NORMAN** read a paper on the Clinical Features of Beri-beri, analysing the symptoms in some detail. Heart troubles were the most serious. An invariable condition was tachycardia with extreme irritability of the pulse. Unconformability of the heart and pulse was frequent and striking. Variable murmurs most commonly heard in the pulmonary area were not infrequent, also reduplication of the first or second sound. The heart was frequently dilated and this dilation (chiefly affecting the right side) often came on with singular [illegible] lity. Death from heart involvement [illegible] rring quite suddenly and in [illegible] after a prolonged ag occurring primarily in the lower extremities, and sometimes confined to the legs, consisted of various degrees of superficial anæsthesia and hypæsthesia combined usually with paræsthesia and hyperæsthesia (painful anæsthesia). Deep (muscular) tenderness and tenderness of the nerve trunks co-existed with loss, diminution, or alteration of superficial sensation. Spontaneous pain (aching and cramps in the muscles, painful formication in the skin) was common. Œdema, in Mr. Norman's opinion, was probably always present, though sometimes very slight and transitory. It varied in character, being usually less marked than in ordinary anasarca, say from Bright's disease, and sometimes approaching closely to the "solid œdema" of the myxœdematous state. It might be slight, fugacious, and confined to the pretibial region, or it might spread all over the body. Cases which were highly œdematous constituted the so-called "wet form" of beri-beri. Effusions into the joints were rare, but common in the serous cavities, especially in the pleura and pericardium. In the latter situation they often accelerated death which might be also brought about or hastened by œdema of the lungs. The motor symptom was paralysis of various muscles or groups of muscles. The muscles first attacked were usually those supplied by the peroneal nerve. The gait in well-marked cases was characteristically neuritic. The greater engagement and less resistance of the extensors gave the shifting equilibrium in standing, the dropped and inverted foot, the high action in walking (*démarche du stopper*). The paralysis rarely involved the upper extremities. The muscles of respiration not rarely suffered, particularly the diaphragm, a fact which constituted one of the dangers of the disease. Beri-beri appeared to be spreading. Since 1894, when, as his audience were aware, it first appeared in the Richmond Lunatic Asylum in Dublin, epidemics had been reported from two asylums in the United States, a few cases strongly recalling beri-beri had been reported from German Asylums, and an epidemic had occurred in the autumn of 1697 in an asylum in the South of France which attacked 150 patients of whom about 40 died.—Dr. SMITH, Dr. LITTLEDALE, Surgeon-General POTTER, and others having discussed the paper, Mr. NORMAN, in reply, said that Manson's opinion that the poison of the disease lurked about the soil of buildings seemed to be supported by appearances. He could not explain why beri-beri should occur chiefly in asylums in this country and amongst the epileptics in those institutions.

SECTION OF PATHOLOGY.

Agglutinability of the Typhoid Bacillus.—Exhibition of Specimens.

A MEETING of this section was held on Jan. 13th, Dr. J. M. PURSER, the President, being in the chair.

Dr. E. J. MCWEENEY read a note on the Agglutinability of Different Races of the Typhoid Bacillus. He described how he had been obliged to suspend temporarily the sero-diagnostic work at the Mater Misericordiæ Hospital owing to the peculiar behaviour of a strain of typhoid fever bacilli, called, for brevity's sake T.A., which he had isolated by the usual methods from the bile of a fatal case of typhoid fever. Death had occurred in this case from cardiac failure nine days after defervescence and at the necropsy the ulcers in the small intestine were healed but there were many open follicular ulcers in the colon. The bacillus T.A. was present in the bile in great numbers and pure culture. It presented the cultural characters of genuine Eberth's bacillus. Distinctive peculiarities were the extreme slowness of its growth on gelatin plates, the fewness, delicacy, and shortness of the flagella, and the fact that although the mobility was extremely active during the first 12 hours of culture it had died down by the end of 24 hours to a waggling movement hardly distinguishable from that of bacillus coli. Tested against the serum of several typical cases of typhoid side by side with a typical race obtained from Professor Lorrain Smith of Belfast it proved markedly resistant against agglutinating influences. The dilutions generally practised were 10 per cent., 1 per cent., 0·2 per cent., and 0·1 per cent. Sera of cases in the third week, which clumped the Belfast bacillus instantaneously in 10 per cent. dilution, and left the field quite clear of isolated organisms, took an appreciable time to clump T.A., and after the lapse of half an hour the field was quite free from scattered bacilli. In the one in 100 dilution, where the Belfast bacillus was well clumped at the end of the observation period (from two to five hours), T.A. was so imperfectly agglutinated that diagnostic inferences could not be drawn—in fact, with the higher dilutions these two races of undoubted typhoid bacilli gave directly opposite sero-diagnostic results. The speaker went on to discuss the significance of the expression "agglutinable" in the light of the recent work published by Kraus and Nicolle, proving that the phenomenon was the result of the interaction of two substances, one contained in the serum, the other in (and subsequently outside of) the bacterial bodies, which played a purely passive *rôle*; he pointed out that the serum need not necessarily be *immune*, nor was the phenomenon essentially specific; and finally, the interesting work of Bordet was described as showing how, quite apart from bacterial action, the serum of the rabbit agglutinated guinea-pig's serum containing red corpuscles, causing these latter to form "clumps," and how, if the serum of the guinea-pig which exercises but a slight agglutinative action on the corpuscles in rabbit serum be taken from a guinea-pig which had previously had rabbit's blood injected a few times, the agglutinative action of the guinea-pig serum was greatly increased.

Dr. KNOTT exhibited 19 Femora and 19 Tibiæ presenting various anatomical, anthropological, and pathological peculiarities; three of the femora were affected with coxa vara.

Mr. CONOLLY NORMAN exhibited a specimen of Peritoneal Tumour which occurred about the junction of the jejunum and ileum and appeared to spring from the peritoneum covering the anterior wall of the intestine; it was of oval shape, of about the size of a goose's egg, and in colour and consistence, both externally and on section, strongly resembling a uterine fibroid. The growth had penetrated the intestine, an irregular ulcerated surface, not fungating, and of about the size of a sixpence, showing in the gut. The patient died from repeated hæmorrhages from this point. No other new growths were discovered and the uterus and ovaries appeared to be perfectly normal. In Mr. Norman's opinion the tumour was a sarcoma.—Dr. E. J. MCWEENEY and Dr. A. R. PARSONS were inclined to think that it was a myoma.

Dr. COLEMAN exhibited: (1) A Glioma of the Cerebral Hemisphere; (2) a Tuberculous Tumour of the Cerebellum; and (3) an Abscess of the Cerebellum.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 3rd in the society's rooms at the West London Hospital, Dr. S. D. Clippingdale, President, being in the chair.—A discussion on the Treatment of Appendicitis was introduced by Dr. Seymour Taylor and Mr. McAdam Eccles and was carried on by Dr. Donald Hood, Mr. Keetley, Mr. Bidwell, Dr. Cayley, Mr. E. T. A. Boyton, Dr. George Eccles, Mr. Lunn, and Dr. Dobson.—Dr. Seymour Taylor considered that the physician's advice was of great weight in two periods of the disease—(1) the preventive period when by so ordering the patient's diet and mode of life an attack of appendicitis might be postponed or even prevented; and (2) when a local tumour having formed the progress of the disease might be arrested at a point short of the formation of pus. Suppuration having occurred, treatment must be entirely at the hands of the surgeon. In the first stage the diet should be largely of a liquid character but should also consist of vegetables and some beef extract. Milk should be rigidly excluded, as it tended to constipation with bulky or scybalous stools. In the second stage his experience was strongly in favour of treatment by perfect rest, small doses of opium frequently repeated, and the administration of copious enemata of soap-water and olive oil.—In reviewing the surgical treatment of acute inflammation of the vermiform appendix Mr. McAdam Eccles said that he considered that surgical interference was called for in all cases where there was suppuration, whether local or remote, in instances where there was general septic peritonitis, and in many cases between attacks, so that the offending organ might be removed. When an abscess in the right iliac fossa had to be dealt with he thought that two points needed emphasis: one that a very free exit for the pus should be secured and the other that nothing more than free drainage, as a rule, should be attempted. His belief was that most patients thus treated did well and had but little tendency to be again troubled with the appendix. He laid stress on the fact that he thought that it was not advisable to explore the area of suppuration until time had elapsed so that peritoneal adhesions, shutting off the general cavity of the peritoneum, might have formed. The pus did not usually tend to pass into the serous cavity and therefore too early operation was a mistake.

The Medical Guild, Manchester.—The annual meeting of the Medical Guild was held in the Victoria Hotel, Manchester, on Jan. 25th, the President, Alderman Walmsley, J.P., M.R.C.S. Eng., being in the chair.—The annual report of the council stated that continued progress had been made during the year and recounted various subjects of professional interest which had been dealt with, including hospital reform, club practice, provident dispensaries, the Midwives Bill and the Vaccination Bill, and the establishment of a quarterly journal for the promotion of the objects of the Guild. 46 members had joined, 15 had resigned (10 being due to removals to other districts), while three had died during the past year. Laudatory reference was made to the Wigan Guild of which practically every practitioner in the district was a member. The treasurer's statement showed a balance in hand of over £16. The annual report and statement of accounts were received and adopted on the motion of the chairman, seconded by Professor Dixon Mann and supported by Dr. Wahltuch and others. The following office-bearers were elected:—President, Alderman F. H. Walmsley. Honorary Vice Presidents: Dr. Henry Ashby, Dr. C. H. Braddon, J.P., Dr. Samuel Buckley, Mr. William Crosby, Dr. J. Dreschfeld, Dr. A. M. Edge, Dr. C. E. Glascott, Dr. Alfred Godson, Dr. James Hardie, Mr. Francis Hepworth, J.P., Mr. Thomas Jones, Dr. David Little, Dr. T. N. Orchard, Dr. D. Lloyd Roberts, F.R.S. Edin., Dr. Henry Simpson, Mr. F. A. Southam, Dr. Graham Steell, Mr. Walter Whitehead, F.R.S. Edin., Dr. S Woodcock, J.P., Mr. G. A. Wright, and Mr. A. H. Young Council: Chairman: Professor J. Dixon Mann. Vice-chairman: Mr. R. H. Wolstenholme. Honorary treasurer: Dr. C. G. L. Skinner. Honorary secretary: Dr. Alexander Stewart. Ordinary members of Council: Mr. Samuel Bagley, Dr. W. Bruce Bell, Dr. Isaac Blore, Mr. William G. Booth, Dr. Robert Forsyth, Dr. Alexander Fraser, Mr. C. R. O. Garrard, Dr. John H. Godson, Dr. N. C. Haring, Dr. Arnold W. W. Lea, Dr. J. W. Grange, Dr. Herbert Lund, Dr. J. Ratcliff-Gaylard, Mr. F. Leyland Roe, Mr. Alic Phillips, Dr. A. Brown Ritchie, Dr. J. Prince Stallard, Mr. G. A. Wright, Mr. A. I. Richards, and Dr. F. H. Worswick. Auditors: Mr. J. W. Wood and Dr. J. C. Nichol.

Folkestone Medical Society.—A clinical evening was held on Feb. 1st at the Victoria Hospital, the President, Dr. Tyson, being in the chair. Thirteen members were present.—A letter was read from Mr. E. D. Fitz-gerald thanking the society for its vote of condolence on the death of the late President, Dr. C. E. Fitz-gerald.—The President showed cases of Myeloid Sarcoma of the Superior Maxilla removed six months ago with no recurrence; Carcinoma of the Mamma operated on with subsequent Atrophy of an Enlarged Thyroid; Tabes Mesenterica with Pyloric Obstruction by Glands; Encysted Hydrocele of the Cord and Tuberculous Tarsus and Ranula.—Dr P. Lewis showed a girl, aged 16 years, who had had the Left Breast removed for Hypertrophy; also photographs of an Apparatus designed to Educate Patients to Breathe through the Nose after Operation for Adenoids; also photographs of Graves's Disease with Unilateral Exophthalmos and no Thyroid Enlargement but in which Tachycardia and Graefe's Sign were present; a case of Myxœdema before and after treatment; a specimen of Calcified Fibroid; samples of Sterilised Milk; a new form of Aspirating Syringe; also Skiagrams.—Dr. Cecil Latter showed a case of Congenital Heart Disease and also specimens of Carcinoma of the Stomach.—Mr. Barrett showed a patient with Advanced Epithelioma of the Lip, also a photograph of another similar case.—Dr. Eastes, Dr. Larking, and Mr. Linington showed Microscopical Specimens.

Neurological Society of London.—The annual meeting of this society was held on Feb. 2nd, when the newly-elected President, Dr. W. H. Gaskell, F.R.S., delivered an address on the Meaning of the Cranial Nerves, in which he gave an account of his researches into the morphology of the cranial nerves, especially in the scorpions and the ammonocœtes. There was a very large attendance of members and at the close a hearty vote of thanks was proposed by Professor Schäfer, seconded by Dr. Ferrier, and carried by acclamation. During the evening the ballot for the officers for 1899 was taken and the following were elected:—President: Dr. W. H. Gaskell, F.R.S. Vice-Presidents: Dr. Julius Dreschfeld and Dr. Augustus Waller, F.R.S. Council: Mr. C. A. Ballance, Mr. R. Marcus Gunn, Mr. Victor Horsley, F.R.S., Mr. J. N. Langley, F.R.S., Dr. C. Mercier, Dr. F. W. Mott, F.R.S., Dr. G. Vivian Poore, Sir Felix Semon, Dr. H. H. Tooth, and Dr. W. Hale White. Treasurer: Dr. Charles E. Beevor. Editor (*ex officio*): Dr. A. De Watteville. Secretaries: Dr. J. S. Risien Russell and Dr. W. S. Colman. Sir Samuel Wilks who was an original member of the society and was its second President was unanimously elected an honorary member. The next meeting of the society will be a clinical one and members intending to show cases are requested to communicate with one of the honorary secretaries as soon as possible.

Æsculapian Society of London.—A meeting of this society was held on Feb. 3rd, the President, Mr. D. H. Goodsall, being in the chair.—Dr. Arthur Davies showed a woman, aged 46 years, who was the subject of Myxœdema. The patient, who had been shown before the society previously to commencing the thyroid treatment, had now lost 6·5 kilogrammes in weight and had gained in brightness and well-being since taking thyroid 0·3 gramme daily for two months. Dr. Davies also exhibited a woman, aged 61 years, a subject of Myxœdema for 16 years, with the characters usually present.—The President showed a much-thickened and chronically inflamed Bladder of only 90 cubic centimetres capacity. The ureters were dilated and there was pus in the renal pelves resulting from a very tight urethral stricture in a man, aged 58 years.—Dr. B. G. Morison related a case of Abortion in a Multipara, aged 53 years, with Retention of the Decidua which was digitally removed. At its completion there was collapse with a pulse of from 120 to 130 per minute, not the result of profuse hæmorrhage. Two hours later the patient again became collapsed when a saline enema of about one litre was slowly given. The pulse improved quickly after commencing the enema and in two hours she had fairly recovered. She did well subsequently.

Reviews and Notices of Books.

Cerebral and Mental Symptoms in relation to Somatic Disease, Anæsthetics and Toxic Agents, Traumata and Surgical Procedures. By JAMES CHRISTIAN SIMPSON, M.B., C.M., M.D. Edin. London: John Bale, Sons, and Danielsson. Pp. 192. 1898. Price 5*s.*

THE subject matter of this book was presented as a thesis for the degree of M.D. of the University of Edinburgh in 1895. Dr. Simpson has done well in publishing it in book form. So much interesting matter is contained in its pages that it would have been a great loss if a greater means of publicity had not been secured for it than would have been possible if the thesis had met with the ordinary fate of such literary productions.

The book is divided into five parts. The first deals with the Cerebral and Mental Symptoms in relation to Somatic Diseases. The subjects brought under discussion offer a pleasant change from t[illegible] ordinary text-books. Each system of the body is dealt [illegible]ly. Thus we have a discussion of the mental sy[illegible]ted with disorders of the alimentary system, ne[illegible]atory system, then of the hæmopoietic system, an[illegible]r the last named we find the mental symptoms noted in Graves's disease, myxœdema, cretinism, &c. Some interesting cases are detailed under the various divisions.

Part II. deals with Toxic Insanity. After a general discussion of the clinical groups into which this condition may be divided the author draws attention to one notable symptom—viz., aphasia—which may be produced by a variety of toxic agents, especially the vegetable drugs belonging to the natural order atropaceæ. Attention is also directed to the toxic insanity which occasionally follows the inhalation of one or other anæsthetic agent when administered for therapeutic reasons. The effects of such drugs as opium, Indian hemp, sulphonal, cocaine, phosphorus, &c., also receive due notice. The sub-section of toxic insanity due to auto-intoxication is also well worthy of perusal. The importance of this form of poisoning has only recently been recognised in this relation, although, of course, the fact of reabsorption of toxic agents from the alimentary canal in particular has long been well known. Gastro-intestinal disturbance occupies a prominent place in this section and the importance of lavage of the stomach and aperients in cases of acute melancholia is insisted on.

In Part III. we find a description of Traumatic Insanity and the cases are divided into those in which there is actual cranial or cerebral lesion and those of a more general nature without actual gross cranial or cerebral injury. Dr. Simpson has evidently made a careful study of the literature of the subject and the various views of authorities such as Mickle, Lamartine, and many others are quoted and discussed.

Part IV. will be especially interesting to surgeons as it deals with the Surgical Relief of Cerebral and Mental Symptoms. The classification is similar to that adopted in Part I. The various systems of the body have been considered in turn, but some preliminary remarks are made on (1) the effect of an operation in an insane patient; (2) whether it is justifiable to operate on insane patients for diseases other than fatal ones; and (3) whether it is justifiable always to operate on an apparently sane patient with a bad hereditary history or an acquired neurosis in cases other than those of fatal disease. These questions open up large fields for differences of opinion and the author's criticism of the various views which have been put forward is marked with firmness and shows a full grasp of the subject. In this division also we find a consideration of the condition of microcephaly and its treatment.

In Part V. an account is given of those cases of Insanity or Mental Disorder which are apparently directly caused by Surgical Operations.

Taking the book as a whole we can cordially congratulate the author on his work which shows every evidence of a thorough and practical knowledge of the subject and we can recommend its perusal to our readers.

A Text-Book of Practical Therapeutics. By H. AMORY HARE, M.D., B.Sc., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Seventh edition. Illustrated. London: Henry Kimpton. 1899. Pp. 731. Price 21*s.*

No greater evidence of a book proving successful could be found than the fact that a sixth edition—a large one—was exhausted in nine months. This has happened with the work now under consideration. Only a few months ago a review of the sixth edition appeared in our columns in which we described the general scope of the book and expressed the high opinion which we had formed of it. But few further words from us are therefore required.

The present edition has been enlarged, thoroughly revised, and brought up to date, and the text has been conformed to the British Pharmacopœia of June, 1898. It is consequently equally as useful to the English practitioner as to the American. One of the greatest advantages of the book is the ease with which any doubtful point can be referred to, thanks not only to a copious index but also to the manner in which each section is arranged. A number of illustrations designed to elucidate descriptions of technique or therapeutic results have been inserted. These are well executed and certainly add to the value of the work. We may repeat the words of our last notice: "We can thoroughly recommend this book to practitioners and students."

General Nursing. By EVA C. E. LÜCKES, Matron to the London Hospital. London: Kegan Paul, Trench, Trübner and Co. 1898. Pp. 351. Price 5*s.*

WE are told in the preface of this excellent manual that the bulk of the contents of this volume was first published in 1884, and that only slight alterations were made in subsequent editions. The instructions in nursing had hitherto appeared in the form of lectures, but the present volume has been entirely re-written and taken out of the lecture form. The result is one of the best books for nurses on their duties that we have yet met with. Written in admirable style, it gives directions which if all nurses would follow would greatly add to the well-being and comfort of the patients whom they are called upon to tend. Much useful advice is given and each page contains some valuable hint or fact. For instance, on the second page is a sentence which too often the nurse is apt to forget, thereby through pride or over-confidence in herself being frequently brought into unpleasant relationship with the medical man in attendance: "Trained nurses must scrupulously avoid anything which approaches to amateur doctoring, not only for their own sake but for the sake of the whole nursing profession. It prejudices all who come in contact with it against the education of nurses and is held in as much contempt by all really accomplished nurses as any other sort of quackery is by duly qualified practitioners." The arrangement of the book leaves little to be desired. By means of headings in black type at the borders of the letter-press reference to any particular point is greatly accelerated. The manual is most complete and any nurse will find it a very valuable addition to her nursing outfit

---

LIBRARY TABLE.

Harry Ingleby, Surgeon. By FREDERIC J. WEBB. London: T. Fisher Unwin. 1899. Price 6*s.*—Mr. Webb gives no indication as to whether he is a medical man or not, but from the internal evidence of his vividly written book we think he must be. We should imagine him to be a young worker in the field of fiction, for the plot of his book—if, indeed, it can be said to have a plot—is crude and even common-place. The trials of a pair of young lovers, the dark, handsome and of course wicked man who intervenes, the seduced dressmaker, and the illegitimate baby are all well-known material and have been used *ad nauseam*. But let us turn from these pieces of padding to Mr. Webb's life-like scenes of general practice in a north country town and in the East-end of London. Here he is thoroughly at home and writes as one who has undergone the trials, worries, and, be it said, the amusement of a practice among the poor. Who of us has not seen this sort of thing? "How the people clustered, too, in the house of the dying, leaving the sufferer no air. The slatternly woman, often drink-stained, seemed to have nothing else to do but hover round saying in subdued tones 'God's good.' ...... On one occasion he held the door open to let thirteen out of one small room. As most had different remedies to propose no wonder the baby died. How essential was a beautiful funeral." Dr. O'Gorman's Irish patients, too, are delightful—the Southern Irish, we mean, that strange, lovable, illogical, contradictory people which combines, as perhaps none other does, the heroism of manhood with absolute childishness. Introductory addresses are still given at most of the hospitals and Mr. Webb produces an admirable specimen. The speaker, Dr. Campbell, does not make out, as is too often the custom, that the medical profession is a bed of roses. Not so; he says: "Your failures will be many, your disappointments heartrending ...... you must not look for rewards or riches or gratitude. ...... Reverence the dead, compassionate the living, be courteous to the poor." Mr. Webb has given us a series of life-like pictures of medical men and medical practice and we commend his book to all who are interested in either subject.

The Secret of Good Health and Long Life. By HAYDN BROWN, L.R.C.P., L.R.C.S. Edin. London: James Bowden. 1898. Second Edition.—This is a little book of some 150 pages but it contains a good deal of sound common-sense. The points to which the writer draws attention are just those which are most commonly neglected. Thus in the chapter on food he says: "Vegetarianism is a boon and a blessing to men because it helps to indicate to us the happy medium; it encourages a certain quantity of vegetables being consumed with other food that might not be taken otherwise." So, too, his remarks on beer are eminently sensible. Reason must have her say, he tells us, and because one man can drink a quantity of beer it does not follow that everyone can, neither because a person can keep well without alcoholic drinks does it follow that nobody else requires them. We can cordially recommend this unpretending little volume and if on the whole the advice given may seem to be a counsel of perfection there is all the more reason for trying to attain to such.

Manual of First Aid. By J. A. AUSTIN, M.D. Aberd. London: Sampson Low, Marston, and Co. 1898.—There is rather a plethora of manuals upon first aid. Fortunately they all say more or less the same thing—that is, as regards broad principles—otherwise the student of first aid might get bewildered with the multitude of counsellors. Dr. Austin's little book is well and interestingly written. In his opening chapters especially he gives various striking instances of the value of first aid given in the right and in the wrong way. The plan of the book follows the syllabus of the St. John Ambulance Association and is copiously illustrated with diagrammatic figures which are plain and simple and also accurate, except, we should say, Fig. 29, showing compression of the brachial artery. As given in the figure the fingers are simply lifting up the biceps. The description of how to compress the artery given in the text is, however, plain enough. Altogether the book is a good specimen of its class.

JOURNALS.

Blackwood's Magazine appears as a double number in honour of reaching its thousandth issue, an event which has been announced as unparalleled in periodical literature. A claim has since been put in for the *Gentleman's Magazine* as showing a longer continuous life. In this number of *Blackwood* the "*Noctes Ambrosianæ*" are revived and the third—or is it the fourth?—generation of *Maga's* contributors are well represented in its pages. Among the contents are stories by Mr. Joseph Conrad and Mr. Maurice Hewlett, the winners of the Academy's £50 prizes for the best books of last year.

Charing-cross Hospital and Medical School have decided not to be behind other large centres of medical education in the matter of being represented by an official organ. No. 1, vol. 1 (January, 1899), of the *Charing Cross Hospital Gazette* has just been issued and its 12 pages contain matter that is well selected and edited. The "School Notes" are merrily done. We bid our youthful contemporary welcome.

New Inventions.

NEW SELF-RETAINING DRAINAGE TUBING.

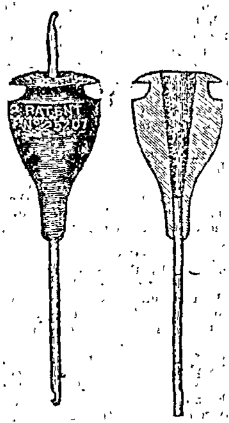
I DESIRE to bring to the notice of the profession a new form of drainage tubing, practically self-retaining, which I have found to answer admirably. It consists of ordinary drainage tubing of various sizes, perforated along its entire length at intervals of about three-quarters of an inch and between each perforation on either side of the tubes are studs or wings which, being of the same elastic material as the tube and cast together in one mould, offer but slight resistance during the process of introduction. As the drained tissues close around the tube these studs offer points of resistance which effectually prevent its slipping out. My suggestion has been very well carried out by Messrs. Arnold and Sons of West Smithfield.

T. CARTER WIGG, M.D. Brux., M.R.C.S. Eng.

Oxford-terrace, Hyde-park, W.

VACCINE EXPELLER.

WE have received from Mr. J. H. Montague of 101, New Bond-street, W., an appliance which promises to be very useful to vaccinators. It is intended for the expulsion of lymph from capillary tubes without resorting to the time-honoured method of blowing it out with the breath and is made wholly of soft, red indiarubber without any attachments of glass or metal. The illustrations show it full size, both entire and in section. The tube of lymph with ends still sealed is first drawn midway through the larger opening as represented; the upper end is then broken off and the tube is drawn still further through until only about half an inch of it remains within the expeller. The other end of the tube containing the lymph is now broken off, and the expeller being held between the first and second fingers the lymph is instantly forced out by placing the thumb over the upper opening and compressing the indiarubber. The lymph may also in like manner be distributed as desired. If the tube does not pass with ease through the small end of the opening in the indiarubber it is only necessary to wet it a little.



FIRST REPORT OF THE ROYAL COMMISSIONERS ON THE METROPOLITAN WATER-SUPPLY.

(Concluded from p. 314.)

THE sixth section deals with the objects to be gained by connexion of the various systems of supply. The Commissioners point out that intercommunication to be of use must necessarily imply that there will be an amount of water available for transfer through the connexions made. Intercommunication would necessarily be useless in the case of a company which was not in the effective possession of a supply of water larger than it required to meet the maximum daily demand of its own customers. The effective possession of such a supply implies that a company has a [illegible] the water and the necessary [illegible] -tment and pumping of the [illegible] is the duty of every company to provide against any contingencies which may arise and they give it as their opinion that each company therefore ought to be in effective possession of a surplus supply. With regard to the possession of a surplus supply the Commissioners state that it should as far as practicable be insured by a proper system of control. Should a general scheme of intercommunication be carried out it should be arranged that in the case of any accident happening, or if as a result of miscalculation on the part of any company as to their resources the result was that they found themselves in want of water, then the defaulting company would be able to obtain the necessary assistance. But after such a proof of incapacity the defaulting company should be made to extend its own works without delay and to remedy defects which had made themselves apparent. By this means the ability on the part of other companies to give temporary assistance would save the population from any interference with the continuity of their water-supply. The Commissioners point out that the engineers of the companies distinguish between major and *minor emergencies. A minor emergency might arise from* a fracture of the mains, from accidents to the machinery, or from great loss of water due to its use for fire extinction. The characteristics of these minor emergencies are that they are usually strictly localised and of short duration, so that the ter[illegible]orary assistance which would be required could be given by a simple connexion of the mains of one company with [illegible] its next neighbour. The major [illegible] arise from failure of [illegible] the sources of supply in the rivers, storage reservoirs, or wells. An illustration of a major emergency was given in the [illegible] of the East London Company during last year. Su[illegible] required the assistance of a large quantity of [illegible] period extending over many weeks and such an[illegible] could only be provided against by laying down [illegible] for the conveyance of water. The Commis[illegible]sioners point out that the schemes of intercommunication [illegible] submitted to them and the principles on which they were drawn up were sound in the case of companies working [illegible] as separate organisations, each of which was under statutory obligations, and they [illegible] that should the various undertakings be amalgamated [illegible] by one authority such intercommunication [illegible] in continuous use.

[illegible] contains observations on the schemes [illegible] submitted by the associated com[illegible] [illegible] observe that the schemes sub[illegible] illustrate the fact that it is practicable to [illegible] whole of the different systems of supply now [illegible] by the eight metropolitan water companies, [illegible] ations and combinations which might be formed for [illegible] these systems are almost infinite in number, and [illegible] changes must take place as the systems extend. With regard to the Battersea scheme it is pointed out that the filter[illegible] of the Southwark and Vauxhall Company should "in no case be permanently continued," as the surroundings render the site unsuitable for such a purpose. The Commissioners state that all the schemes submitted to them appear to be feasible and that either would be a good insurance against failures if each company had effective possession of a surplus supply of water to transfer and if the statutory restrictions on intersale of water were abolished or suspended.

The eighth section is devoted to a consideration of the cost of the intercommunication scheme and to the legal powers which it would be necessary to obtain for carrying it into effect. The Commissioners point out that the East London were the only company in default during last summer and that the subject of intercommunication became one of urgency in consequence of that default. They consider that the companies take "a wide and sound view" of their obligations in viewing the intercommunication system as one of joint benefit to all. They commend the resolutions of the companies as set forth at the commencement of the report. In the opinion of the Commissioners the cost of connecting the different systems should be defrayed by money raised by issuing debenture stock from time to time. The Commissioners agree with the suggestion that whilst the works *of intercommunication are not* used the total amount of debenture stock issued by any of the companies should be treated as a common fund and that the companies should contribute to the payment of interest in proportion to their water rentals. If the works of *intercommunication* are used the company receiving water should pay an amount in such proportions of the interest on their debenture stock as may be agreed upon by the companies or in case of disagreement by some sum to be fixed by an arbitrator. A company receiving water should also pay at a price to be agreed upon or to be fixed by the companies or should they not agree by the President of the Local Government Board on the application of any one company. The Commissioners report that in their opinion the debenture stock raised might properly be exempt from the obligations of a sinking fund clause. The Commissioners point out that the London County Council had opposed any intercommunication scheme on the ground that it might increase the value of the undertaking, but they give it as their opinion that an arbitrator would not consider that the values were increased by intercommunication and they observe "that no company should be allowed in the event of purchase to enhance the value of its undertaking by means of an intercommunication scheme." The scheme is intended, they point out, to keep up a full supply for which a company receives payment in water-rents and to protect water consumers from inconveniences which may be due to an accident or more frequently *to default of some company* in making due provision to carry out its supply. The Commissioners say that further consideration is required to determine exactly what works it would be best to undertake to ensure efficient intercommunication. It would not, they believe, be expedient to lay down a complete scheme in a Bill and they recommend in preference that elastic clauses should be framed so that the companies may execute from time to time any works which may be authorised by some public department such as the Local Government Board. To guard against possible dilatoriness on the part of any company the Bill should contain a provision to ensure that any works authorised or [illegible]ected by the Local Government Board should be im[illegible]tely carried out. The Commissioners are of opinion [illegible] the case of intercommunication being established [illegible] companies it would be better for the work to be carri[illegible]ltogether by one of them and that therefore it would [illegible]ll to empower companies to execute works within and outside their statutory limits of supply. The Commissioners give a list of Acts which at present are or may be statutory impediments to an efficient system of intercommunication. These are:

1. The Staines Reservoirs Act, 1896, which prohibits sale of water impounded in those reservoirs.

2. The Southwark and Vauxhall Company's Act, 1898, which prohibits the sale of water abstracted from the Thames under the provisions of that Act.

3. The Thames Conservancy Act, 1894 (Section 295). A somewhat complicated question of law arises out of this Act and on the true solution of the points raised the Commissioners refrain from expressing an opinion.

The Commissioners state *that* it has also been suggested that the powers of the companies under the Waterworks Clauses Act or under the private Acts which they at present possess are sufficient to authorise them to take up streets and do other works which may be necessary for the purpose of *carrying* out the scheme.

With regard to the question of further abstraction of water from the Thames the Commissioners report that the suggestion that the Local Government Board should have power in the case of emergency to authorise an additional draught on the Thames is one which would be likely to meet with opposition. They point out that the time at which the Local Government Board would be asked to use its power of dispensing with the statutory obligations of the companies would be at times when the Thames was low and when any further depletion of the river would be objected to. The Commissioners suggest that it would be better to extend to all the companies the principle contained in the Staines Reservoirs Act and *to* allow them to draw a varying amount of water from day to day provided that the quantity drawn per day on an average of six months does not exceed the authorised amount; they see no good reason why the companies should be bound to a fixed maximum quantity in every 24 hours and they suggest that the reservoirs might be rapidly filled at times when the river is full. In conclusion the Commissioners point out that the recommendations in the report are entirely independent of the matters contained in the other two references which have been submitted to them and that their suggestions in no way prejudice the question of control to be exercised by local or other authorities or the question of purchase of the companies' undertakings by one or more authorities.

THE LANCET.

LONDON SATURDAY, FEBRUARY 11, 1899

THOUGH it is somewhat premature to speak of the General Medical Council having drafted a Bill for the amendment of the Medical Acts it is a fact that on one or two points affecting the disciplinary powers of the Council a practical unanimity seems, or rather seemed, to have been reached by that body when in May last it was resolved on the motion of Mr BRYANT seconded by Dr MACALISTER —

> That the President be requested to communicate with the Lord President of the Privy Council as to the practicability of obtaining such an amendment of the law as will more effectually prevent the holder of a medical diploma or degree from using the title thereof after his name has been erased from the Medical Register under Section 29 of the Medical Act, 1858, and for so long as the erasure continues in force

This is the fundamental action of the Council in the matter It is due to the President to say that he has been diligent in the promotion of the movement in the way of communications with the Privy Council and with the qualifying bodies At first he did not meet with much encouragement He received from Sir C LENNOX PEEL an intimation that the Lord President could not hold out any hope of legislation being undertaken to effect amendment of one provision alone of the Act even if the degree giving bodies had expressed a desire for the amendment, which did not appear to be the case Nothing daunted, the President at the instigation of the Executive Committee undertook further correspondence with the Privy Council and fortified himself with two clauses calculated to facilitate the discussion of the amendment, as to the necessity for which there seemed a practical unanimity in the Council The clauses were drafted at the President's request by Mr MUIR MACKENZIE and are as follows We quote from the minutes of the Executive Committee dated Nov 26th 1898

1 Where a registered medical practitioner has been convicted in England or Ireland of any felony or misdemeanour, or in Scotland of any crime or offence or has after due inquiry been judged by the General Medical Council to have been guilty of infamous conduct in a professional respect, the General Medical Council may if they see fit by order, to be made either at the inquiry or at any subsequent time direct that the name of such medical practitioner shall be and remain erased from the Medical Register for a limited period to be specified in the order, and may from time to time by subsequent order or orders vary such period, and at the expiration of the period specified in any such order or subsequent order the Registrar shall unless otherwise ordered by the General Medical Council, restore the name of the practitioner to the Medical Register

2 Where the name of a registered medical practitioner has been erased from the Medical Register by order of the General Medical Council for any of the causes specified in Section 29 of the Medical Act 1858 such practitioner shall for as long as his name remains erased from the Medical Register be deemed to be deprived of every diploma or degree conferring a qualification to practise medicine surgery, or midwifery possessed by him Any practitioner who in contravention of this section shall use the name title, or description of any diploma or degree of which he is by this section deemed to be deprived shall be guilty of an offence under Section 40 of the Medical Act, 1858 and all provisions of the said Act in relation to offences under the said section shall apply accordingly

It will be seen that the object of the above clauses is twofold—first, to give clear power to the General Medical Council to erase the name of an offending practitioner for a limited period and at the expiration of that time to restore the name, and, secondly, to provide that while such period lasts the said practitioner shall be virtually deprived of all titles and qualifications entitling him after registration to practise, so that any such practitioner who does practise in contravention of this provision will be guilty of an offence under Section 40 of the Medical Act The clauses meet two great defects in the existing powers of some of the qualifying bodies—the inability to withdraw in the case of an offending practitioner the titles and qualifications which they have given, and the want of power to restore the same when the period of punishment has passed It is notorious that in some of the most serious instances of crime or professional offence the offender still retains his title and, if he is not in prison continues to practise on the strength of it On the other hand, it is equally well known that many of the offences for which men are removed from the Register are of such a nature as not to call for the erasure of their names for more than a limited period but many licensing bodies have not the power to restore their names Unless these defects can be remedied either names which should be removed will be permitted to remain on the Register or gross injustice will be done by inflicting a permanent disqualification when only a temporary one is called for

It will be seen by our report[1] of the proceedings of the Royal College of Physicians of London that this body objects to the second clause Even if it has already ample powers of discipline in its own hands, we do not see why the College should object to a general clause giving uniformity to the law of punishment We cannot but hope that further consideration will induce that corporation to fall in with the general demand that all licensing bodies should be brought into coördination with each other through the General Medical Council for the public weal and for the measured and uniform punishment of offences against the public good The universities were supposed to be the only obstacle in the way of such legislation They have taken a public spirited view of the question, and we hope that the Royal College of Physicians of London will upon reflection withdraw its objection Without unanimity it is hopeless to go to the Privy Council or to Parliament With unanimity it seems probable that this great anomaly may be effectually stopped As we understand the matter, however, this question is so far only in the preliminary stage The General Medical Council has not yet had a chance of hearing the results of the inquiry by the President as to the attitude and feeling of the qualifying bodies towards these two clauses. Still less has it had the opportunity of expressing itself as to the necessity for the amendment of other parts of the Medical Acts which in the judgment of many greatly need alteration. Possibly when this question of the amendment of the Medical Acts comes before the General Medical Council other questions will be raised, so that the objection of the Lord President to deal with the amendment of one provision alone will no longer have force. It will be something gained, however, if unanimity can be secured with respect to these two clauses which seem to make no unreasonable demand on the qualifying bodies.

---

[1] THE LANCET Feb 4th 1899, p 335

A RECENT report drawn up by the medical officer of health to the London County Council—Mr. SHIRLEY MURPHY—effectually sums up the case both for public control in regard to supply of milk and for the abolition of private slaughter-houses In this commendably short but pregnant report Mr. SHIRLEY MURPHY expounds the position under both heads in such decisive terms as should leave little doubt as to the proper steps which should be instantly taken for the elimination of a double reproach on this branch of our sanitary administration. The report deals first with the statements of the deputations which attended before the Public Health Committee of the London County Council on Nov. 3rd, 1898, on the question of the proposed abolition of private slaughter-houses in London and with the representations subsequently made to the committee on the subject. It was drawn up in consequence of an instruction given by the chairman of this committee. The views of Royal Commissions on the subject of private slaughter-houses and the ills that may arise out of them are well known, clear, and decisive, and the question remains for consideration as to how to give effect in London to the recommendations enjoined. In regard to milk Mr. SHIRLEY MURPHY points out that the following administration is necessary. The owners of cows in London will be required to notify to the Council every case of disease of the udder. As is well known the latest Royal Commission stated that according to their experience the conditions required for ensuring to the milk of tuberculous cows the ability to produce tuberculosis in the consumers of such milk is tuberculous disease of the cow affecting the udder. The Council will employ a veterinary inspector to examine all cows with diseased udders and determine the nature of the disease; and if this be found to be tuberculous the cows will be slaughtered. Periodical inspection of cows in cowsheds will be needed with a view to enforcing the requirement of notification, for the Council will require the slaughter of all cows affected with tuberculosis of the udder or exhibiting clinical symptoms of tuberculosis. If, when the animal is slaughtered, it is found that an error in diagnosis has been made the Council will compensate the owner of the cow. Further, samples of milk sold in London will be taken and milk vendors will be required to supply sufficient information as to the sources from which the milk is derived. If such milk is found to be tuberculous the Council will require from a local authority in whose district the cows are situated "full information and veterinary reports concerning the cows, byres, &c.," and if dissatisfied with the report will, with the sanction of the Local Government Board, make an independent inspection of the cows. Obviously the Council will require the aid of a laboratory specially set apart for this purpose. The recommendations of the Public Health Committee concerning milk-supply have not met with opposition and it is to be hoped therefore that the clauses each and all will soon be adopted in order that the sale of tuberculous milk may be limited if not altogether stopped. One small omission we notice. We do not find any reference to the milk imported from Holland and elsewhere into this country. We believe that the importation of frozen milk is rapidly growing and clearly this milk should not be left beyond the pale of administrative control.

In regard to inspection of meat, there were several dissentient views expressed by members of the deputations who addressed the committee and directed in the main to the question of the abolition of private slaughter-houses. Some said that this abolition would "practically destroy the purchase of English farmers' cattle," for "the only customer practically so far as London is concerned is the man who has a private slaughter-house of his own." Others said that the metropolitan cattle market of the City Corporation "might almost as well shut its gates"; butchers "would neither take the trouble nor would they go to the extraordinary expense and inconvenience of sending their servants to a public slaughter-house in order that they might slaughter the animals which have been bought." As a matter of fact where the system of control suggested has been tried, as on the continent, it has been found to be, as the result of a number of years of experience, not only a valuable protection to the public but acceptable to all honest butchers. Moreover, the members of the Royal Commission on Tuberculosis who visited Germany reported that "all the public slaughter-houses in Germany are self-supporting" and there is no reason why this should not be so in London or in every city and town. In elucidation doubtless of this view, Mr. SHIRLEY MURPHY's report is accompanied by a communication from the architect of the London County Council upon the public slaughter-houses in continental cities visited by him. Mr. SHIRLEY MURPHY deals ably with the various objections raised by the sanitary authorities in London who have communicated their view on the subject to the Public Health Committee. These objections bear chiefly on the question of cost.

In reviewing the whole subject it is perfectly clear that the objections raised to a systematic inspection and control of our meat-supply and milk-supply dwindle into the merest insignificance compared with the infinitely broader, and more important question of the preservation of the health of the community. The action of the Legislature is therefore most urgently and promptly needed in this matter. As Sir RICHARD THORNE in his excellent Harben Lectures has ably said, "The properly administered public slaughter-house is demanded as an act of justice to those trading in meat; it is demanded in the interests of public health and decency; it is demanded for the prevention of cruelty to the lower animals; and it is demanded in order to bring England, if not the United Kingdom, somewhat nearer to the level of other civilised nations in this matter." To which sentiment we have nothing to add.

◆

WE publish to-day the third and concluding part of our summary of the first report of the Royal Commission on the Metropolitan Water-supply. We must congratulate the Royal Commissioners on the promptitude with which they have dealt with the evidence which has been given to them on the subject of the intercommunication of the water companies' mains, a subject which forms one complete division of the reference which was entrusted to them. The report given by the Commissioners on this point is to the effect that a well-considered scheme of intercommunication is not only useful but necessary in the interests of the water consumers, and in making their report the Commissioners are careful to point out that the carrying into effect of such a scheme will not prejudice in any way the question of the advisability of the purchase of the water companies' undertakings, or the question as to whether it is advisable that the water companies should be placed under more stringent control. The advisability of an increased number of intercommunications between the companies' mains has been rendered urgent by the failure of the supply of the East London Waterworks Company during last summer. We have already insisted that everything possible should be done to ensure an adequate supply of water for East London next summer and we have pointed out that it is highly desirable that some temporary provision to make good the deficiencies of the supply of the East London Company should immediately be made. We are glad to see that the recommendations of the Commissioners are fully in accord with what we have already advised on this subject. The Commissioners do not commit themselves to the details of any of the schemes of intercommunication which have been brought before them, but they emphasise the fact to which we have already called attention that the present Battersea station of the Southwark and Vauxhall Company ought not to be used for a longer period than is absolutely necessary. The proposals of the associated metropolitan water companies with regard to intercommunication which were laid before the Commissioners and which we have already published *in extenso* have been embodied in a Bill of which we give a summary in our present issue (v. p 396). After the recommendation of the Royal Commission that some system of intercommunication ought to be immediately adopted so that the East London Company may be enabled to give a constant supply during the present year there can be no doubt that Parliament will promptly deal with the question and that an Act will be speedily passed to effect this purpose. Some of the provisions of the Metropolitan Water Companies Bill need careful consideration and some, in our opinion, should in the public interest be considerably modified before the measure is allowed to pass into law. We must, however, for the present content ourselves by congratulating the people of East London on the probability that they will this year be free from the inconvenience and suffering to which they have recently been subjected by the failure of the East London Waterworks Company to give them an adequate supply.

Annotations.

"Ne quid nimis."

THE QUEEN'S SPEECH.

IT is impossible to peruse the Queen's Speech without being struck by the great and growing importance of disease prevention and of the conservation of the physical well-being of the people as matters of legislative and administrative concern. The Upper House is told by Her Majesty of the unremitting efforts which are being made to prevent the extension of plague in the Indian Empire and to provide relief for its victims. The measures taken to deal with the distress in the West Indies consequent on the great hurricane form the subject of another paragraph. The Commons are told that the water-supply of the metropolis is to engage attention, that the Factory Acts are to be amended, that further legislation to prevent the adulteration of food is to be undertaken, and that local authorities are to receive additional powers with regard to the housing of the working classes It can hardly be denied that the beneficent educative influence of the medical profession on public sentiment and opinion has been one of the causes to which is due the fact that such legislative proposals as these bulk largely in Parliaments at the present day. As practitioners of the healing art medical men are continually engaged in battling with existing disease. Both individually and in various corporate capacities they are at the same time doing their utmost to remove the causes of diseases, and many Acts of Parliament and many organisations for the promotion of social welfare owe their origin and the principles which inspire them, to medical initiative and advocacy. While, however, the Queen's Speech contains much that is excellent in purpose, a large part of which we were able to forecast last week, its most remarkable feature from a medical point of view is its absolute silence on one question which at the present time is most needful of legislation, is ripe for legislation, and has been the subject of what amounts almost to Ministerial promise of legislation. Needless to say, we speak here of revaccination. Whatever be the faults of the conscience clause—and as it stands in the statute book and is being administered in the country they are numerous enough and manifest enough—it at least has the great compensating advantage that it opens wide the door by which a large and statesmanlike measure of revaccination may be introduced. Indeed, no conscience clause should ever have been proposed or passed without the accompaniment of a revaccination clause But the Government's policy in vaccination matters appeared to be guided by no principle, and it was only when a second reverse threatened them in the House of Lords that at the last moment they succeeded in obtaining the invaluable support of Lord Lister, and through him of a majority of the Lords present, by means of statements which could not be looked on as very far short of pledges regarding legislation for revaccination to be considered in the recess and to be introduced when Parliament should again meet. As the most distinguished member of the medical profession in Parliament, as the member who, having first satisfied himself of the intentions of the Government on this subject, thereupon publicly stated that he was satisfied and so saved the Government from defeat, it is impossible for Lord Lister to allow the matter to be passed over and we are convinced that he has no intention of permitting it so to rest. No man knows better than the Chairman of the Jenner Institute the great and immediate need that exists for the protection of the adolescents and that need has been intensified by the very Act which he succeeded in getting his colleagues in the House of Lords to accept even after the Prime Minister had failed. Some strong man, if Lord Lister does not come forward, must make it his business to see that the Government, for their own credit and above all for the public welfare, make no undue delay in fulfilling not merely the letter but the spirit of their expressed intention, and introduce, not at the fag-end of the session but in ample time for its safe passage through Parliament, a measure which shall at least place revaccination on the same footing with primary vaccination as regards statutory requirement and provision for its performance. Independently of any pressure by the medical profession or by the better educated of the general public the mere self-respect of the Government requires that they shall introduce and pass such a Bill, and it is surely out of the question to suppose that they can have any other purpose. In the general interests of public business it is important, however, that an immediate announcement should be made on the subject and we regret that such an announcement has been omitted from the Queen's Speech.

THE REGULATION OF STREET TRAFFIC.

WE are proverbially slow to move in administrative affairs in this country and especially in London, so that when at last steps are taken the movement appears drastic. The recent police order prohibiting the "crawling" of cabs along certain of our thoroughfares is a case in point. The order has brought both convenience and inconvenience to the travelling public. There is less impediment to the great omnibus traffic, but there are much fewer chances of engaging a cab at any point. Indeed, during the past week persons have had literally to "hunt" for a cab or to walk to the nearest rank. Whether this regulation is a hardship to "cabby" or not is a question with which we have little to do. It is to be hoped, however, that other regulations will be extended to omnibuses with a view to improving the services and we should like to see the equipments of this vehicle improved also. It is a notorious fact that there are too many omnibuses on the London roads. The omnibus may be stopped with few exceptions at almost any given point which inevitably leads to a congestion of traffic only equalled by the "crawling" cab. We have on a previous occasion urged that the omnibuses should have recognised calling stations and that they should be forbidden to stop for the purpose of picking up pedestrians at any point other than a recognised or official stopping place. We are surprised that the omnibus companies do not themselves adopt this plan, since considerable wear and tear (especially as regards the horses) would be saved while the service would be materially accelerated. Further, by such a system the chances of accidents arising from the omnibus failing to stop on passengers leaving or entering the vehicle or of the horses starting at a critical moment would be reduced to *nil*. This we should have thought would have appealed to the companies purely on the score of avoiding compensation claimed for injuries arising through such circumstances. It is quite certain that our street traffic can be improved under stricter police regulations. The number of omnibuses running to and fro should be reduced or else the greater number of them should be compelled to avoid the congested thoroughfares. For example, the omnibuses going west and east might be made to take the Thames Embankment as a clear and "through" route to and from the City. We are sure that it would pay the companies to run some of their vehicles by way of the Embankment from the City to Charing-cross. A large proportion of the passengers getting into an omnibus at Charing-cross going eastwards require to go the whole way to Liverpool-street, and *vice versâ*. The omnibus itself needs considerable improvement. There is not comfortable room for 12 persons inside. The lighting is often inadequate and absolutely precludes reading. The outside of an omnibus is so much lost carrying space in wet weather. Cannot this be obviated? Even when the rain ceases the accommodation provided is not only uncomfortable but dangerous. There can be little doubt that the aprons which have been well soaked in a shower of rain are responsible for many a chill with serious sequelæ. Now that our police authorities seem to be seriously taking steps for the better regulation of vehicular traffic it is to be hoped that improvements will be commenced all round. They are certainly needed, but all kinds of vehicles contribute towards blocking the way and the regulations therefore should be made to apply uniformly.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: THE WEBER-PARKES PRIZE.

WE would call the attention of our readers to the fact that the second award of the Weber-Parkes prize and medals (to be awarded triennially to the writer of the best essay upon some subject connected with the etiology, prevention, pathology, or treatment of tuberculosis, especially with reference to pulmonary consumption in man) will be made in 1900. The adjudicators have selected as the subject of the essay for that occasion—"The Ætiology of Human Tuberculosis and the Assistance which a Knowledge of the Ætiology may render to the Task of Prevention." The essay must be based on the original work and observations (experimental or other) of the author and must include a detailed exposition of the methods employed and their mode of application. The value of the prize is 150 guineas and a silver medal. A similar medal, distinguished as the second medal, will be awarded to the essayist who comes next in order of merit. The award will be made on some day previously to Oct. 18th (St. Luke's Day), 1900.

MOSQUITOES AND MALARIA.

IN THE LANCET of Nov. 12th, 1898 (p. 1300) our Rome correspondent mentioned that Dr. Amico Bignami, *privat-docent* in pathological anatomy in the University of Rome, working in concert with Dr. Dionisi, also of Rome, experimented in 1896 on the possibility of engendering malarial fever by means of the punctures of mosquitoes. Our correspondent returned to the subject in THE LANCET of the following week (Nov. 19th, p. 1371), *adding that it had been* alleged that Dr. Bignami's mosquito hypothesis dated as far back as 1894 and furthermore giving an outline of a controversy as to priority of discovery which had arisen between Dr. Bignami and Dr. G. B. Grassi, ordinary professor of comparative anatomy in the University of Rome. In the first of these two letters our correspondent wrote that Dr. Grassi "succeeded last summer in completing a series of observations by which he ascertained and determined the mosquito tribes which had power to convey the disease." It appears, however, that the mosquito theory of malarial fever was not then by any means broached for the first time, for we have now before us a portion of the printed proceedings of the Philosophical Society of Washington, D.C., United States of America, showing that on Feb. 10th, 1883, Dr. A. F. A. King read a paper entitled "The Prevention of Malarial Diseases, illustrating *inter alia* the Conservative Function of Ague." After enumerating 20 theories or maxims relative to the genesis of malarial fever the abstract of Dr. King's paper proceeds as follows: "These generally admitted facts were insusceptible of scientific explanation by the marsh fever hypothesis of Lanscisci (*sic*), but were capable of explanation by the theory that marsh fevers are produced by the bites of proboscidian insects, notably in this and in some other countries by mosquito bites A review of the natural history, habits and geographical distribution of the mosquito was next presented in explanation of the 20 statements above quoted In discussing statement 15 [i e, that of all human races the white is most sensitive to marsh fevers, the black least so] it was maintained that the comparative immunity of the black races was largely due to color, the dark complexion of the skin being another illustrative instance of 'protective coloring' so often observed in other animals and by which, in this instance the negro was protected from the *sight* and consequently *from the bite of the mosquito*, a similar protection being further secured by the offensive odor and greasiness of his cutaneous secretions In further support of the mosquital origin of malarial fevers numerous noted medical authorities were cited, showing that in all parts of the world where these diseases prevail immunity was secured by protecting the body from mosquito bites The geographical distribution and seasonal evolution of mosquitoes and other proboscidian insects were shown partially to agree with the times and places in which malarial diseases prevail though from lack of information conclusive evidence on this point was yet wanting The abstract concludes with suggestions for the prophylaxis of malarial disease by personal protection from all winged insects especially during evening and night by gauze curtains veils, &c, and by inunction of the body with terebinthinated, camphorated, or eucalyptalised ointment or liniment

THE WORKMEN S COMPENSATION ACT.

THIS much abused—almost universally abused—Act has now been in operation for upwards of six months, and so far as its administration in the neighbourhood of Newcastle is concerned it must be a great disappointment to its framers We were told that the Act would diminish litigation, but so far the exact opposite has been the result Every day cases are reported in the newspapers as settled in court on the old lines An action is brought in the county court the usual contradictory evidence is given, and the case is adjudicated upon as it would have been had no such Act been passed, with the result that should the masters lose or win they are saddled with considerable legal expenses The services of the official referees are not called into requisition and so far as that principle is concerned the Act seems to be a dead letter The number of accidents has very much increased to the manifest advantage of the lawyers and those members of the medical profession appointed by the masters, the men, and the insurance companies to look after their interests The men seem hardly more satisfied with the Act than the masters, and as time goes on this piece of legislation and similar legislation which it is said is sure to follow must have the effect of still further separating the men from the masters The effect will be far reaching and nowhere is it likely to be more felt than by the medical charities Subscriptions to these organisations from the employers are already being diminished and are likely to cease altogether The so called workman who is only allowed to work for eight hours a day will have to support the hospitals and dispensaries himself—which indeed, he is well able to do Not only so, but the aged and in any way damaged man whether from physical infirmity or moral propensity, will inevitably cease to be employed The trades unions will not allow a man to work for less than the wage which a strong man can earn, and this again will throw more men out of employment for the masters will be only too ready to dispense with their services It remains to be seen how the great mutual societies such as the Northumberland and Durham Miners' Permanent Relief Fund, will be affected At present both men and masters contribute to this really splendid fund for the relief of those accidentally hurt and for aged members It is more than likely that the masters' contributions will be withdrawn If so the society will cease to support members injured by accident and will provide old age pensions only for the members It is certain that some means will have to be devised other than the Poor law for the advantage of men deprived of work under the Workmen s Compensation Act—men who but for such legislation would have continued at work for some years

THE WEATHER IN 1898

THE exceptional warmth and drought of 1898 are well brought out by a series of observations taken at Sevenoaks by Mr W W Wagstaffe, F R C S Eng The differences between the maximum temperatures for each month and the corresponding figures obtained from 10 years' observations at Sevenoaks were as follows —January, 7° higher; February, 4° higher, March 2° lower, April, 1° higher, May, 5° lower, June, 4° lower, July, 1° higher, August, 2° higher, September, 8° higher, October 5° higher; November, 2° higher, and December, 7° higher The actual maxima for each month were as follows —January 54° on the 30th February 55° on the 1st March 60° on the 18th April 64° on the 8th May 73° on the 22nd and 23rd June 75° on the 18th, July 80° on the 15th and 16th August 85° on the 14th and 22nd September 88° on the 8th October 64° on the 2nd and 3rd November 58° on the 10th, and December 55° on the 4th The average maximum for September was 71°, being the highest average for any month of the year, The rainfall for the year was 20 65 inches being 11 41 inches less than the average of 10 years at Sevenoaks The rainfall was below the average in every month of the year except May

MIDWIVES AS ILLEGAL PRACTITIONERS IN NEW YORK

THE *Medical Record of New York* has recently published an instructive article on the midwives question in that city by Mr Eldridge T Gerry, President of the New York Society for the Prevention of Cruelty to Children Previously to 50 years ago the midwife in the United States was practically a monthly nurse working with the regular medical man in charge of the case The influx of foreigners since then has introduced the midwife in all the forms and with all the prejudices of the particular country from which the foreigner has come The article shows that the development of the midwife has been disastrous to children and often to women who have been admitted into homes and hospitals enjoying a sort of protection under articles of incorporation under the Hospitals Acts The incorporators are usually the immediate relatives and friends of the midwife and persons of no *locus standi* perhaps living in other States In such homes pregnant women are treated Abortion is often procured The children are neglected Sometimes they are left in the street, sometimes they are "adopted,' and in the latter case blackmailing operations are often tried on respectable people who have ' adopted them and perhaps come to be attached to them The midwife in charge of such a home assumes the title of doctress and offers to "treat female diseases" "irregularities guarantees success in every case, undertakes confinements, &c, &c This evil has grown to such an extent that legislation has been procured requiring the certificate of the State Board of Charities to approve the organisation and incorporation of such institutions and authorising the Board to apply to the Supreme Court for the cancellation of a certificate of incorporation of institutes not having the approval of the State Board. Unfortunately, the State Board does not seem to have been very active in the use of its powers. In 1893 the Society for the Prevention of Cruelty to Children took action and secured the conviction of several notorious keepers of so-called "lying-in asylums" who advertised ostensibly for that purpose in the daily papers, but whose places were used for the purpose of criminal abortion. One typical instance is given in which Magistrate Pool expressed a strong opinion that the managers of the corporation were mostly relatives of the defendant; that the defendant was not lawfully authorised to practise medicine, but called herself a doctress and conveyed to unsuspecting persons that she was a legal practitioner of medicine, &c. The writer of the article points out that the case has not yet been disposed of in the trial court. Meantime the evil is great. One of the difficulties, the writer of the article suggests, is that there is no registration of midwives by competent authority and that no physician attends the home. He thinks "the remedy is very simple' and it consists of a Bill requiring the registration of midwives, making it penal for a woman to practise without registration, and placing the control of the matter and of the midwives in the hands of the local county medical society, with power to remove from the list those who violate the provisions of the Bill. In addition there should be a proviso forbidding any incorporation of such midwives with other persons for any purpose incidental to, or connected with, their business. It is interesting to notice that in New York as in Chicago this kind of legislation is almost forced on the legislature by the scandals of untrained and uncontrolled midwives.

INDIAN AND COLONIAL STUDENTS IN EDINBURGH.

ON Jan. 27th a meeting was held in Edinburgh to consider the question of providing a residence or residences for the Indian and colonial students attending the University. The circular calling the meeting had been signed by Professor Crum Brown and Professor Prothero. At the meeting the chair was occupied by Sir William Muir, and among those present were: Professor Sir William Turner, Professor Sir Thomas Grainger Stewart, Professor Rutherford, Professor Crum Brown, Professor Seth, Professor Wallace, Professor Prothero, Professor Kirkpatrick, Professor Geddes, and Sir T. Batty Tuke. A report was given of what had been done in London towards promoting the educational federation of the Empire. From the statistics it was shown that last year there were in all 227 Indian and colonial students in attendance at the classes of the University, exclusive of those who were attending extra-mural classes and other teaching institutions. There was probably more Cape-Dutch spoken in the University than Gaelic. The number of colonial students had, however, been rather on the decrease during recent years, this being due partly to the improvement of University teaching at Cambridge and other English medical schools, partly to the increase of residential facilities at other universities, and partly also to the fact that English universities had strengthened their ties with colonial universities by recognition of a two-years' study towards graduation and by other points in connexion with scholarships, &c. Recently one of the colonies had enacted that its students holding scholarships should only attend residential universities, and residential facilities would probably soon be established in connexion with the re-organised University of London. The Australian Club and the South African Union, though useful places, did not supply the want. A residential colonial house would be a means of bringing together all the colonies and of fostering a sympathetic and statesmanlike spirit. Sir William Muir moved and Professor Prothero seconded: "That this meeting cordially approves and warmly supports the suggestion of providing a residence or residences for the use of members of the very large body of students attending the University from the colonies and India; and also that this meeting expresses its sympathy with the work already done by the London committee and pledges itself to support their efforts." Professor Crum Brown moved, "That a committee be appointed to forward the matter in conjunction with the London committee and to arrange for a joint meeting to be held in Edinburgh at a subsequent date." Both motions were carried. The first meeting of the committee thus appointed was held on Jan. 3rd at the University Union. Several general suggestions were brought forward which met with the approval of the committee. It was agreed that a maximum of 25 residents should be adhered to as the most suitable number for the residential colonial houses and that it would be advisable eventually to have a separate house for each colony, although in the meantime this might not be practicable. It was estimated that the sum required for each house furnished, and including a reserve guarantee against possible deficiencies, would amount to from £5000 to £6000. The amount might be raised privately by colonists and other interested individuals, and ultimately applied to the erection or purchase of buildings, while the income from the funds might meantime be employed in renting one or more houses as might be required. These buildings might be managed by special committees appointed by the University Court which should have as conveners representatives of the Colonial Government.

BACTERIOLOGY OF TYPHUS FEVER.

TYPHUS fever has undergone a great decline in both England and Scotland during the last 30 years and has been comparatively rare in London for 20 years. An outbreak having occurred in Edinburgh last November, as mentioned in THE LANCET of Dec. 3rd and 10th (pages 1509 and 1588), Dr. Andrew Balfour and Dr. Charles Porter, members of the staff of the Edinburgh City Hospital, took advantage of the opportunity presented for bacteriological investigation and have published a preliminary notice of their results in the February number of the *Edinburgh Medical Journal*, with the reservation that "it is not intended at present to make any comments on this research nor to put forward as yet any theory regarding it." Seven cases of undoubted typhus fever were examined *post mortem* and in all of them a diplococcus was found. In six of these cases an examination with the usual precautions was made of blood from the heart, the spleen, and the lung. In four of the six cases the diplococcus was present in each organ. Of the remaining two, one showed the organism in both spleen and lung but not in the heart, while the other exhibited it in the lung only. In the seventh case the examination was limited to the spleen. Microscopically, under the ordinary high power the organism appeared as a well-marked diplococcus, apparently about 2 μ in transverse diameter, with no appearance of a capsule. It stained well with carbol fuchsin or gentian-violet and retained the stain by Gram's method. In some instances it tended to occur in chains, tetrad formations, and small clusters, but generally it was found as a separate diplococcus. It grew rapidly in broth and milk and seemed to possess the power of coagulating the latter in from 24 to 48 hours. It was easily cultivated on agar, blood serum, Löffler's blood serum, and potato. There was no formation of gas in glucose jelly. The most favourable temperature for its growth appeared to be 37° C. Blood from the thumb in 19 undoubted cases was examined by means of films, hanging drops, and broth cultures. 15 of these were acute cases, ranging from the fourth to the fourteenth day of fever, and in every case large numbers of diplococci were found after the broth had been incubated at 37° C. for from 12 to 48 hours. Many of the cases were examined on several occasions and at no time was the diplococcus absent. In addition, seven control cases were examined, one being a case of scarlet fever, one of measles, the others being cases exposed to the infection of typhus fever but showing no symptoms of the disease. In only one of these, a quarantine case, was the diplococcus present, in reference to which the suggestion was made that the patient, a boy, might have already had a slight and unrecognised attack of typhus fever.

SEWER VENTILATORS.

THE sewer ventilators in our streets are an abomination and more especially when they are not elevated. They cannot be dispensed with, as otherwise the evil emanations of a sewer would probably be forced up into the houses and thus a worse state of things would be established. But at least these ventilators should be raised well above the average breathing level instead of being sunk at the street-level pouring forth disgusting and poisonous stenches immediately under the pedestrian's nose. As a correspondent has pointed out in a recent communication to us bearing on the prevalence of diphtheria, this disease is most common in houses abutting on the sewer ventilators. The distribution of the poisonous gases can be easily traced in cold weather, when a foul vapour can be seen rapidly issuing from the ventilator. The elevation of these ventilators would not entirely remove the evil, but it would considerably diminish the danger which now arises. Children, as our correspondent says, play about the jaws of the death-traps which yawn for them by hundreds in the narrow roads of our poorer districts and into the houses of which drift the foul air and vapours through each open door and window. This is a serious indictment and calls for the abolition of street-level sewer ventilators in favour of the elevated ventilators which have been adopted in many places with a marked favourable influence on the public health.

TUBERCULOSIS AND SECONDHAND CLOTHING.

MR. ANTONY ROCHE, Professor of Public Health at the (Roman) Catholic University of Dublin, has been delivering a very admirable lecture upon the Cause and Prevention of Consumption to an audience of Dublin artisans. We are all the more grateful to Professor Roche for this step because whatever boards of health and the various sanitary authorities may do the prevention of consumption must lie very much in the hands of the people themselves. Professor Roche drew attention to a point which is not, perhaps, as much insisted on as it should be—namely, the facilities for the spread of infection offered by the sale and barter of secondhand clothing. "Clothes," he says, "may not be a very common medium for the spread, still the tailoring of clothes in overcrowded workshops with the possible infection from one or more sufferers among the workmen or women is a possible danger; so is the buying of the secondhand clothes which may have been worn by consumptive owners and also the storing of infected clothes in the warehouses of pawn-offices. I long ago advocated the compulsory disinfection of all clothes in pawn-offices by the sanitary authorities as a safeguard against the spread by them of this and other infectious diseases." With regard to cheap tailors' workshops much has been done since Mayhew in his "London Labour and London Poor" drew his graphic pictures of the unhealthy workshops and "Parson Lot" fulminated with all the strength of his fiery nature against the same evil, but much still remains to be done. As to pawnshops we doubt whether anything has been done, and they certainly are likely to be fruitful sources of infection. Professor Roche's lecture ought to do a great deal of good. The artisan, though naturally ignorant upon hygienic matters, for he has never been instructed, is by no means a fool and will, we are sure, do his best not only for himself but for his neighbour when he understands the necessity for action.

AN ASSOCIATION OF SCHOOL GOVERNORS.

WE have received what we suppose we may call a prospectus of a new association to be entitled "An Association of the Managers and Governors of Schools for the Working Classes in the United Kingdom." The document is very lengthy, but so far as we gather it proposes to bind together all managers or governors of working-class schools into one association. The Association is to confine itself entirely to secular education and the subscription per member is to be 5*s*. Among other matters the association is to work for the object of getting the whole cost of the education of the children of the working classes paid for by the contributions of the whole community. This is an object with which we are in hearty accordance, for as at present constituted the education rate is the most unfair and preposterous of all the taxes which the long-suffering ratepayer has to provide. The circular is signed by Mr. C. E. Luard, a county councillor for Kent, and he announces that Mr. C. G. Montefiore of 12, Portman-square, has consented to act as provisional trustee of any funds entrusted to Mr. Luard towards the objects of the Association. We are glad to see this noted for Mr. Montefiore's name is so closely connected with good work done in the matter of education that the fact of his showing interest in the Association should augur well for its future usefulness.

THE VACCINATION OF WORKHOUSE CHILDREN.

IT is not the least fault of the Vaccination Act of 1898 that it is likely to be the subject of endless debates and discordant interpretations. The "satisfaction" of the magistrate as to the "conscientiousness" of the objection of a parent is an insoluble difficulty to be removed only by being ignored. We are threatened with a Parliamentary debate on quite another point—the legality of an "offer to vaccinate" by a medical officer of a workhouse any child resident in a workhouse at the age of two months. Mr. Channing, the member for East Northamptonshire, finds that the form of vaccination contract with the medical officer of a workhouse in the second schedule of the order of Oct 18th empowers and compels the medical officer to make such an offer. Mr. Channing, with the genuine Northamptonshire antipathy to vaccination, sees in this a violation of the section of the Act which extends the age for vaccination from three to six months and expressly provides that no pressure shall be put on the parent till four months. He has made his complaint to the Local Government Board. The Board has replied that they see nothing in Paragraph 2 of the vaccination contract to be entered into between guardians and the medical officers of workhouses which is inconsistent with the Vaccination Act of 1898. The peculiar circumstances of workhouse life, especially of children born in workhouses, whose parents generally leave the workhouse before the age of four months, suggest and justify the "offer" of vaccination to such children. No pressure is intended to be applied to the parent who though a pauper may have the sense to see the advantage of the early vaccination of her child before leaving the workhouse and of accepting the "offer" which the order in question has very properly provided. Mr. Channing and his friends will do well to be content with the temporary victory which they have gained over the intelligence of Parliament and not to provoke discussions on this most questionable legislation. Sub-section 5 of Section 1 of the Bill, introduced at the instigation of Mr. Channing and accepted by Mr. Chaplin, was not to prevent the "offer" of vaccination at two months but to secure the same law of vaccination for the inmates of workhouses as for those outside.

MUNICIPAL BACTERIOLOGY.

THE indefatigable Dr. Waldo, medical officer of health for the Vestry of St. George-the-Martyr, Southwark, has met with a rebuff in his crusade against disease. He recommended some time ago that the vestry should undertake the bacteriological examination of doubtful cases of typhoid fever and diphtheria. Camberwell has already done this and there is no reason that we can see why other parishes should not do likewise. This proposal would involve the distribution of sterilised tubes to practitioners for the collection of cultivable material. But the Public Health Committee of the vestry would have none of it and so at the meeting of the vestry held on Jan. 24th a motion was carried to proceed no further in the matter. Wisdom, however, will, we are sure, prevail in the end.

THE INEBRIATES ACT, 1898, AND THE HOME OFFICE.

THE Home Secretary has addressed to the judges, chairmen of quarter sessions, and recorders a circular letter on the administration of this Act which may be summarised as follows. A certain number of certified reformatories may be expected to be established and ready for the reception of inmates by the time the Act comes into effective operation. This date, as we have pointed out in a previous issue, cannot be until the model regulations propounded by the Home Office have lain on the table of each House of Parliament for four weeks. The provision of State reformatories is to be for the present postponed, as it has not been possible to obtain trustworthy statistics as to the extent to which they will be required. It will be remembered that habitual drunkards who are for the fourth time within 12 months convicted of any of certain scheduled offences may be detained for a period not exceeding three years in a certified inebriate reformatory and that State reformatories are only to be used under the Act for the reception of persons convicted on indictment of an offence punishable with penal servitude or imprisonment, when the offence was committed under the influence of drink, or with drink as a contributing cause, and by an habitual drunkard. These persons can be received into certified reformatories as well as into a State reformatory and it is no doubt owing to the uncertainty as to the extent to which the former will be provided by public bodies and private individuals that the Home Secretary proposes to postpone asking the Treasury to provide funds for the institution of the latter. He has considered the possibility of adapting an existing prison for the purposes of a State reformatory and has been strongly advised against it. Consequently he suggests that, on the Act coming into effect committals be made to certified reformatories only. The only other important point upon which he touches is that of the duration of the term of confinement in a reformatory which is to be imposed, and he points out that whereas he has been advised that periods of a few months will be useless for the effecting of any permanent benefit to the person committed, if the full possible sentence of three years' confinement be passed a system of licensing or probationary discharge can and will be always brought into operation as early in each case as the circumstances will allow. In addition to this he calls attention to the model regulations, as showing that the detention will not be of a punitive but of a reformatory character only. It is also stated that information will be obtainable as to the institution most suited for and likely to receive particular cases, the accused being meanwhile remanded or committed to prison. From the above it can be seen that the Act is to be given a fair trial; indeed, the reported remarks of judges and magistrates alike show that the administrators of the criminal law are prepared to welcome its provisions as soon as may be and to make full use of them. At the same time the practical question of where any individual inebriate is to be received is one which in spite of the assurance cited may be of grave difficulty. Obviously those reformatories which county and borough councils institute will only be willing to receive inmates from contributing districts, while private ones may be far to seek; and again public bodies may wait to take steps until the resources of private benevolence within their jurisdiction or within easy reach of it have been exhausted.

GONORRHŒAL ARTHRITIS TREATED BY INCISION AND IRRIGATION.

IN the *Boston Medical and Surgical Journal*, Dec. 29th, 1898, Dr. John Homans has described a case of gonorrhœal arthritis of the knee-joint treated by incision and drainage. A man, aged 25 years, had gonorrhœa and left epididymitis. After three weeks he had pain and stiffness in the knees which persisted in the left knee. The latter became swollen and tender but not red, and the inguinal glands were enlarged. The bursa patellæ stood out very plainly. The urethral discharge was slight and muco-purulent. The joint became larger and the pain kept the patient awake for four nights. A two-inch incision was made over the outer edge of the patella and the capsule was opened. 10 ounces of thin, brownish, sero-purulent fluid were evacuated. The cavity was explored with the finger and several fibrinous flakes were removed. The joint was flushed with normal saline solution at 120° F., sterile wicks were passed through and the cavity was wiped out. A second douching was performed. A gauze wick was drawn through and the ends of the wound were sutured. A dry dressing with compression and a back splint were applied. On the third day the dressing was changed; the synovitis was much diminished and there was a slight serous discharge on removing the wick. On the seventh day the patient was perfectly comfortable and on the eighteenth day he was discharged. Gonococci were not found in the discharge.

POST-MORTEM EXAMINATIONS UPON A CORONER'S WARRANT.

IT will be remembered that in THE LANCET of Jan. 7th we commented upon the perfunctory manner in which a medical man had made a post-mortem examination upon the authority of a coroner's warrant. Another somewhat similar case has now occurred at St. Albans during the holding of an inquest by Dr. Lovell Drage. The facts were shortly as follows. A man was picked up in the street unconscious and conveyed to the workhouse infirmary; he had vomited freely. The workhouse nurse deposed to receiving the deceased who was then conscious but who rapidly became worse. He was admitted at three o'clock and the medical officer was sent for at half-past eight, but the patient was dead when he arrived. The medical officer, Mr. T. P. G. Wells, said that he had made a post-mortem examination and found old pleurisy and general congestion of the lungs. He did not examine the brain. The coroner said he should adjourn the inquest. Post-mortem examinations must be made with completeness. At the adjourned inquest Mr. H. L. Bates said that he had made a post-mortem examination in conjunction with Mr. Wells. He found a large cerebral hæmorrhage This was the cause of death A verdict in accordance with this evidence was returned The coroner censured Mr Wells, pointing out that he (the coroner) had in his order made a special note to the effect that the principal organs were to be examined Mr Wells had not done this and he should disallow his expenses Mr Wells replied that he considered he had found enough evidence in the lungs as to the cause of death and moreover, the post mortem room was anything but luxurious We do not think for a moment that Mr Wells wished to mislead the jury but there is no doubt that he did not perform the post-mortem examination strictly in accordance with the coroner s instructions

BARBER S ANTISEPSIS

THE choice of an antiseptic is a matter of some importance to the hairdresser since his customers commonly expect him to be a man who can furnish them with a so called hair tonic or wash to improve the condition of the scalp and to prevent dandruff or scurf It is a matter of still greater importance to the public, as unwittingly the barber may be administering a hair wash possessing dangerous properties Seborrhœa (dandruff) is a condition caused by a micro organism and an antiseptic is therefore indicated in such a case There are no diplomas granted to the barber with a view of qualifying him for his business and he is not generally a man possessing any knowledge of pharmacy He should on no account therefore be tempted to employ highly poisonous antiseptics Yet a solution of corrosive sublimate is a favourite application with not a few In the majority of cases the hairdresser is quite ignorant of the dangerous nature of such a preparation but under certain conditions as in abrasions mercury would be readily absorbed and mercurialism might result Corrosive sublimate should never be used for the purpose and carbolic acid and other corrosives should be avoided especially as there are a great number of equally effective and comparatively non poisonous antiseptics to choose from Such, for example are salicylate of soda, benzoate of soda, tincture of gum benzoin, borax beta naphthol, and resorcin, with which can be combined such pleasant aromatic as well as antiseptic oils as eucalyptus and thymol

NEW YORK PORT SANITARY DISTRICT

DR A H DOTY the health officer of the port, remarks in his annual report for 1897 that during that year 220 186 immigrants arrived in the United States and of this number no less than 192 004 disembarked at New York It is interesting to observe that nearly half the total number of foreign vessels arriving at New York during the year were British, but we notice also that a very large number of immigrants are carried by German lines The total number of immigrants arriving at New York varies enormously year by year In 1891 there were 445 290, in 1892, 388 486 in 1893, 364,700, in 1894 188 164, in 1895 258 560 in 1896 252 350, and in 1897 192 004 The great falling off in 1894 was caused by the prevalence of cholera in Europe which interfered very markedly with the tide of immigration As regards the inspection of vessels arriving at New York Dr Doty states that the immigrants are in all cases examined but that on the transatlantic or mail steamers the crews and saloon passengers are not as a rule inspected, the deposition of the captain and surgeon being accepted If however a suspicious case of infectious disease has occurred on the voyage or is detected on arrival a thorough examination is made as is also the case when the vessel comes from an infected port more especially from one where yellow fever is present Owing to the prevalence of this latter disease at Panama during 1897 and the occurrence of cases on board vessels bound for New York a sharp look-out was kept. The patients were removed to Swinburne Island Hospital and the remaining steerage passengers were transferred to Hoffman Island for observation during five days the crews being allowed to proceed in the ship to the docks where they also were kept under observation Every vessel arriving from Panama during the prevalence of yellow fever there was disinfected. So, too with regard to persons from Havana it was determined to insist upon a medical examination prior to departure If those wishing to sail were natives or had had yellow fever they were allowed to sail, but otherwise they were kept under observation for five days The ships crews were not allowed on shore at Havana Vessels arriving from Brazil when yellow fever was present were detained at New York for four or five hours only, as the length of the passage was regarded as sufficient quarantine, The cabin and forecastle the clothing of the crews, and the bedding were however, disinfected in all cases We are glad to hear that a bacteriological laboratory has been erected on Swinburne Island and that some useful work is being done thereon

THE JERSEY MEDICAL SOCIETY AND TUBERCULOSIS

THE Jersey Medical Society recently appointed a committee to examine into the question of human and bovine tuberculosis in the island The report is now published and the committee find as follows In the town of St Helier which was chosen instead of the whole island on account of the imperfection of country death registers twenty years ago the tuberculous death rate from 1872 to 1876 inclusive was 542, being a mortality of 4 2 per 1000 living per annum and of 182 5 per 1000 deaths reckoning the population at 27,000 From 1892 to 1896 inclusive the total of tuberculous deaths was 305, being a mortality per 1000 living of 1 05 per annum and 106 57 per 1000 deaths the population being reckoned at 29 000 As to bovine tuberculosis the committee find that it can hardly be said to exist It must be remembered that the Channel Island States have instituted State slaughter houses and recommend that all meat should be killed there and strictly examined The committee would like to see this regulation more strictly enforced than at present In London we have not got as far as that yet 833 years ago the Channel Islands conquered England It is time that we followed our conquerors example

DANGEROUS INCOMPATIBLES

AN important case, but with a sad sequel, has been reported to us by a correspondent in Johannesburg The death of a young woman was caused by the administration of a medicine containing liquor strychniæ in conjunction with liquor arsenicalis We do not know the precise circumstances of the case but it should be instrumental in drawing serious attention to the question as to whether such a combination should be given together in a mixture in a bottle Of course the alkali of the liquor arsenicalis precipitates the strychnine in the form of the pure alkaloid, and the residue, which may amount to an excessively poisonous dose may be taken in the last dose in the bottle We have no hesitation in saying that such a mixture should never be dispensed although we find it stated in books on dispensing that liquor strychniæ and liquor arsenicalis are sometimes prescribed together In this form the alkali of the latter precipitates the strychnine, so that a shake the bottle label must be used.[1] The risk, we consider, is too great to countenance such a mixture being dispensed. The alkaline solution of arsenic should be kept separate from the strychnine and the two should be administered separately in equal quantities. The discretion of the public is too variable a factor to be relied upon to seriously observe the notice to shake the bottle in the case of mixtures likely to contain an extremely poisonous sediment. We may add that the use of the liquor arsenici hydrochloridi would obviate all risk of strychnine poisoning from precipitation.

THE RESPONSIBILITIES OF CERTIFYING FACTORY SURGEONS.

THE Home Office has recently issued a memorandum to certifying factory surgeons reminding them of their duties under Section 29 of the Factory and Workshop Act, 1895. It very clearly states the duties of the certifying surgeon and should leave his mind perfectly clear as to the scope of his energies in this matter. The memorandum contains, however, certain information bearing on industrial lead poisoning which should be useful to the general practitioner. Thus it sums up the symptoms of lead poisoning, diagnosis, and the variety of manifestations met with as a consequence of lead poisoning. In one paragraph it is pointed out that the necessity for notification does not arise until lead poisoning is diagnosed and in general unless the symptoms are of such a nature as to require abstention from work. Explicit directions are further given as to when abstention from work should be ordered. The memorandum is drawn up by Dr. Whitelegge, the Chief Inspector of Factories, and general practitioners, as well as those more closely concerned with the question, will find some points well worth noting.

ADDITIONAL LUNACY AND VACCINATION FEES DUE TO MEDICAL OFFICERS OF WORKHOUSES.

IN another column (p. 407) a correspondent asks a series of questions relating to the fees due to a medical officer of a workhouse for services in connexion with lunatics and vaccinations. In the first place, it may be observed that it makes no difference in either of these matters whether the medical officer is resident or non-resident. Lunacy fees are payable to the medical officer not in virtue of his office but in the capacity of a medical practitioner, and the method of payment is settled under the *Lunacy Acts*. When an alleged lunatic is brought into the workhouse it is the duty of the relieving officer who brought the case to lay information thereof before a lunacy justice or magistrate who then summons a medical practitioner, preferably the medical officer of the workhouse who is already acquainted with the case, to his aid, for which he makes an order on the guardians for the payment of the fee—usually one guinea. The medical man is entitled to that fee for examining and reporting on the alleged lunatic, whether a detention order or an order of removal (certificate of insanity) is made or no; This is a point which is often misunderstood and which cannot be too much insisted upon. The fee is not paid for "certifying" to a person's lunacy but for "examining and reporting upon" an alleged lunatic. The justice cannot, or should not, act without first calling in a medical man—he is directed so to do by the Act—with whose assistance and upon whose report he makes either an *order for 14 days' detention*, or discharges the person there and then, or at once signs the certificate for his removal to an asylum. In any case the medical man is entitled to his fee. If after making a detention order the patient subsequently has to be certified for removal to an asylum by the same medical man—i.e., by the medical officer of the workhouse—which frequently happens, he is not entitled to two fees for the same case, one for examining and reporting at the time of detention and one for certifying for removal. The amount paid is entirely within the discretion of the justice, not that of the guardians who are bound to pay the sum ordered by the justice. When extra trouble is involved or extra distance is travelled a fee of two guineas is sometimes ordered. It is not usually paid "at the time," as suggested by our correspondent, but the medical officer usually presents all the quarter's account to the clerk to the guardians at the end of the quarter as a matter of convenience. As regards the question of vaccination fees, these are settled by the Vaccination Acts and the Orders issued by the Local Government Board in pursuance of the powers vested in them thereby. For the purpose of vaccinating the inmates the workhouse is a "vaccination district" and the medical officer, whether resident or non-resident, is the "public vaccinator" thereof within the meaning of the Act. At the time of his appointment a vaccination contract with the guardians for the performance of vaccinations at a given fee is usually drawn up. The medical officer is entitled to the minimum fee payable to public vaccinators under the Act, unless at the time of his appointment the guardians, with the sanction of the Local Government Board (which is not now usually given), have stipulated that he shall do the vaccinations without a fee. The guardians very rarely allow a higher fee than the minimum, excepting perhaps on the extremely rare occasions when they wish to recompense their officer by some payment which they have been unable to make in another direction, as, for example, a proposed increase of salary which the Local Government Board would not sanction.

FREE MEALS FOR SCHOOL BOARD CHILDREN.

LORD REAY, the chairman of the School Board for London, has forwarded a communication to the daily journals asking the public for a continued and extended financial support to the London Schools Dinner Association which supplies funds for providing cheap or free meals for necessitous children. The object, we need scarcely add, should commend itself to the consideration of benevolent people on the grounds alike of humanity, common-sense, and hygiene, for it is hopeless to expect that without such aid hungry and destitute children can be physically fit to profit from the education which the schools afford. The funds of the association are administered by local committees who see that the distribution of this aid is limited to those who are really in need of it. If we want to maintain a fair standard of health among board school children and to see them grow up physically as well as mentally fit to take part in their future struggle for life provision must obviously be made for feeding their bodies in the case of destitute and underfed children as well as for educating their minds. Donations are received by the honorary treasurer, Lord Kinnaird, 1, Pall Mall East, or by the Secretary of the Association, 37, Norfolk-street, Strand.

A DECADE OF HYGIENIC MAXIMS.

AMONGST 500 competitors Dr. Decornet of Ferté-sur-Aube has been proclaimed the winner of the prize which was offered by the publishing firm of Messrs. Hachette et Cie in their "Annual Almanack" for 1897. The candidates were required to state briefly under 10 heads the most effectual rules for preserving health, mental and bodily. The following are Dr. Decornet's 10 maxims:—1. General Hygiene: Rise early, go to bed early, and in the meantime keep yourself occupied. 2. Respiratory Hygiene: Water and bread sustain life but pure air and sunlight are indispensable for health. 3. Gastro-intestinal Hygiene: Frugality and sobriety are the best elixir for a long life. 4. Epidermal Hygiene: Cleanliness preserves from rust; the best kept machines last longest. 5. Sleep Hygiene: A sufficiency of rest repairs and strengthens; too much rest weakens and makes soft. 6. Clothes Hygiene: He is well clothed who keeps his body sufficiently warm, safeguarding it from all abrupt changes of temperature while at the same time maintaining perfect freedom of motion. 7. House Hygiene: A house that is clean and cheerful makes a happy home. 8. Moral Hygiene: The mind reposes and resumes its edge by means of relaxation and amusement, but excess opens the door to the passions and these attract the vices. 9. Intellectual Hygiene: Gaiety conduces to love of life and love of life is the half of health; on the other hand, sadness and gloom help on old age. 10. Professional Hygiene: Is it your brain that feeds you? Don't allow your arms and your legs to become ankylosed. Dig for a livelihood, but don't omit to burnish your intellect and elevate your thoughts.

THE meeting of the Pathological Society of London on Tuesday, Feb. 21st, will be devoted to a discussion of the nature of Pseudo-tuberculosis. Specimens and lantern slides will be shown and it is hoped that as much material as possible will be brought together; any members willing to contribute are requested to communicate with the secretaries of the society. One of the objects of the discussion will be to obtain a more definite idea as to what lesions should be included under the heading of Pseudo-tuberculosis. Dr. G. Sims Woodhead will introduce the discussion and other speakers will follow, including Professor Sidney Martin, F.R.S., Professor John McFadyean, Dr. J. W. Washbourn, Mr. Pakes, and Dr. Wethered.

MR. H. E ANNETT, M.B., Ch.B. Vict., has been appointed Demonstrator of Tropical Pathology in the newly founded school of tropical diseases in Liverpool. Dr. Annett has been studying in Koch's laboratory in Berlin for the past two years. His career at University College, Liverpool, was a distinguished one. He there obtained the Lyon Jones Scholarship (Senior and Junior) and the Holt Fellowship in Pathology. Dr. Annett was also appointed Research Scholar by the Commissioners of the 1851 Exhibition.

AT an influential meeting of the Medical Committee of the Brompton Hospital for Consumption and Diseases of the Chest held recently, Dr. Green being in the chair, it was unanimously resolved that the new treatment of tuberculosis be tried at that institution, and the subject is now under consideration by the committee of management, together with that of the establishment of a sanatorium in the country, for which funds are urgently needed.

WE regret to learn the death of Mr. Thomas Cooke, F.R.C.S. Eng., which occurred suddenly from aneurysm at 40, Brunswick-square, W.C., on Wednesday afternoon. We shall publish an obituary notice in our next issue. The funeral will take place on Monday next at 2 P.M. at Kensal Green Cemetery.

SUMMONSES have been issued for the usual February meeting of the Executive Committee of the General Medical Council. The meeting will be held on Monday, the 27th inst. Summonses have also been issued for a meeting of the Penal Cases Committee to be held on Tuesday, Feb. 28th.

THE Home Secretary has, in accordance with the provisions of the Inebriates Act, 1898, appointed Dr. R. Walsh Branthwaite to be an inspector under the Inebriates Acts, 1879 to 1898.

A CASE of bubonic plague is reported from Middelburg, South Africa, the patient being an Indian who recently arrived from Bombay.

THE Governors of the Radcliffe Infirmary, Oxford, have received a munificent gift of £2500 from Mr. T. H. Rose of Oxford.

PROFESSOR J. W. BYERS has been appointed Examiner in Midwifery to the Royal University of Ireland for the year 1899

TUBERCULOSIS AND MILK-SUPPLY.

FRESH evidence accumulates day by day of the relation of tuberculosis to milk-supply. We have already published in our columns several communications on the subject which leave little doubt of the risk to which the health of the community is exposed by the consumption of milk infected with the tubercle bacillus. The relation thus established calls for vigorous control of our milk-supplies at home and abroad. Among those who were foremost in taking steps to ascertain how far the spread of tuberculosis could be referred to milk-supply was the City Council of Liverpool. To the credit of one of the members of the Health Committee, Mr. Anthony Shelmerdine, an investigation was started in December, 1896, when at his instance 50 samples were obtained from 50 different milk-sellers in Liverpool and were immediately submitted to bacteriological examination by Dr. Sims Woodhead and Dr. Cartwright Wood. It may be briefly stated as the result of this investigation that of the 50 samples examined five were capable of setting up tuberculosis in guinea-pigs and that accordingly 10 per cent. of the samples of milk under examination must be regarded as being infected with the tubercle bacillus. The individual details of the results of biological experiment are of interest but we may omit the 45 examples which proved to yield negative results both on subcutaneous (three cubic centimetres) and intraperitoneal (two cubic centimetres) injection. As just stated, five samples of milk appeared capable of setting up tuberculosis in the guinea-pigs inoculated. In three of these samples, Dr. Sims Woodhead and Dr. Cartwright Wood remark, both of the animals inoculated developed tuberculosis, while in two other cases only one of the animals inoculated with the milk developed the disease. "As it is a very unusual thing for animals which have been injected with tubercular material to escape the infection we must consider the question why half of the animals injected with these two samples escaped and also the possibility of these animals having contracted the disease otherwise than through the samples of milk with which they were inoculated. When a set of animals are inoculated with the milk containing tubercle bacilli from a cow suffering from tuberculosis of the udder all the animals succumb to the disease. Bollinger, however, pointed out that when such a milk was diluted sufficiently (40 to 100 times) with sound milk the mixture was unable to set up the disease. He concluded from this that the milk from a dairy, in which of course the milk from a large number of cows is mixed together, would probably not be rendered infective as a whole by the presence of the tuberculous milk, but that on the other hand the dilution would tend to render the milk as a whole innocuous. Our knowledge of other disease organisms would certainly lead us to expect that the dilution of the infective fluid would exert great influence on its virulence since it has been proved in the case of certain pathogenic germs that a certain definite number of bacilli are necessary to infect the animal and that where we pass much below this dose the animal may escape. It has also been shown that the dose required to infect varies greatly with different species of animals, and no doubt there is a considerable range in the amount required with different animals of the same species. Wyssokowitschky has tried to determine the number of tubercle bacilli necessary to infect a guinea-pig. He found that from eight to 30 virulent bacilli *introduced into the peritoneal cavity are necessary to* bring about infection of a guinea-pig. No doubt these results are merely approximate, as much would depend on the virulence of the bacilli experimented with and also the individual susceptibility of the guinea-pigs which can, as a rule, be quite safely ignored in an ordinary inoculation but which would here have an opportunity of displaying itself where the quantity introduced is as small as to verge on the minimal quantity necessary for infection. Although, as we have already stated, in our experience all the animals inoculated with the milk from a cow either develop tuberculosis or remain unaffected, according as the udder happens to be affected with the disease or to be free, this need not hold in the case of milk obtained from a dairy. It is quite possible, or even probable, for a tuberculous milk to be so diluted with other milks in a dairy as to be capable of giving rise to the disease in only a certain proportion of the animals inoculated. Under such circumstances we should expect the disease to manifest itself differently and to run a much more chronic course, and this, as a matter of fact, was the case. Indeed, the disease which resulted from the injections of the milks was much less advanced than one would have expected, and as there is often some difficulty in demonstrating microscopically the presence of tubercle bacilli in such cases, we took the precaution of inoculating a second guinea-pig with some of the diseased organ which was suspected to be tubercular. As will be observed where the material was infective the disease ran a much more rapid course than in the animals primarily inoculated. This is to be accounted for by the fact that they probably received a much larger quantity of the infective agent than was present in the original milk. It will also be noted that in the cases infected directly from the milk the disease was sometimes almost localised and did not always appear to spread directly along the track of the lymphatics, but would sometimes appear to make a leap and attack some other organ, such as the spleen or liver. This is a type of the disease which we should expect to meet with where the animals had been inoculated with a weak virus or a small quantity of the infective agent. We are accordingly of the opinion that these two samples of milk contained tubercle bacilli, although the amount of the infective agent present was probably not very large. It may also be suggested, in view of these facts, that we might possibly have been able to demonstrate the presence of tubercle in some of those samples of milk which gave us a negative result if we had brought a larger quantity of the material under examination by inoculating a larger series of animals and perhaps also by allowing them a longer period in which to develop the disease."

The reports of the examination of the samples thus referred to we append:—

SAMPLE (NO. 11 IN THE REPORT).

The "subcutaneous" guinea-pig when killed on the thirty-fourth day was found to be apparently quite healthy in all the organs and no trace of tubercle could be found.

The "intraperitoneal" guinea-pig was killed on the thirty-fourth day. On opening into the abdominal cavity a small yellow point apparently tuberculous in its origin was observed on the abdominal wall. The spleen contained one small nodule but was otherwise unaffected. The mesenteric glands were enlarged and harder than normal but in one case contained a small mass of caseous material from which cover-glass preparations were made and a guinea-pig was inoculated. Microscopic examination showed the presence of tubercle bacilli. The inoculated guinea-pig was killed on the forty-eighth day. The inguinal glands on both sides were enlarged, but not extensively. The spleen, liver, lungs, and glands at the root of the lungs were all extensively tuberculous.

SAMPLE (NO. 44 IN THE REPORT).

The "subcutaneous" guinea-pig was killed on the thirty-sixth day. The inguinal gland on the side of injection was very much enlarged and filled with cheesy pus. Cover-glass preparations of this pus showed the presence of tubercle bacilli. None of the other organs were manifestly affected. A guinea-pig inoculated with the pus from the abscess on being killed 48 days after was found to have developed tubercle. The inguinal glands, spleen, liver, lungs, and glands at the root of the lung were all affected with tubercle.

The "intraperitoneal" guinea-pig was killed on the thirtieth day but a careful examination failed to show the presence of tubercle in any of the organs.

As already stated, three other samples gave immediate evidence of tuberculous infective property.

The direct microscopical examination of these milks for the presence of tubercle bacilli gave in every case a negative result, as indeed might have been expected under the circumstances considering that the infected milk was probably diluted many times with that of sound animals. The probability of the bacilli being present in very small numbers in at least two of the samples was rendered very strong by the fact of only half of the animals inoculated with these milks becoming infected and because the lesions set up were much less marked than is usually the case.

The results of this investigation indicate the desirability in the case of mixed milks—such as are obtained from a dairy—of bringing under examination a larger amount of the suspected milk by making a more extensive series of animal inoculations than has up to the present been usually considered sufficient.

METROPOLITAN WATER COMPANIES' BILL.

WE have already announced[1] that the Metropolitan Water Companies' Bill[2] has passed through the Private Bills Office. The Bill is drawn up very much on the lines suggested in the resolutions passed by the directors of the associated companies which were placed before the Royal Commission now sitting and which were published *in extenso* in THE LANCET of Jan. 28th, p. 242. The Bill, although not of great length, is one of considerable importance; it consists of 24 sections.

The preamble states that it is expedient, with the view to obviate the possibility of a deficiency of water-supply in time of drought or by reason of accident or emergency, that provision should be made for improving the intercommunication between the mains of the different companies, and that the metropolitan water companies ought therefore to be allowed temporarily and with the sanction of the Local Government Board to abstract when necessary an increased amount of water from the Thames. It is stated that since the last session of Parliament certain work has been done by some of the metropolitan water companies which would have been legal had the present Bill been passed by Parliament and it is suggested that the Bill should be retrospective as far as work already carried out is concerned. It is suggested that it is expedient that the water companies, or in their default the Local Government Board, should appoint an arbitrator who should settle any differences which may arise under the Bill, and it is further suggested that the companies should be allowed to raise money on debenture stock to carry out the provisions of the Act. The Acts which it is proposed to incorporate are the Waterworks Clauses Act of 1847 (with respect to breaking up streets, &c.), the Lands Clauses Act (except those provisions respecting the purchase of land otherwise than by agreement), and Part 3 (debenture stock) of the Companies Clauses Act, 1863, as amended by the Act, 1869. All the metropolitan water companies are interested in the promotion of the Bill.

Under the provisions of the Bill it is proposed that within six months after it becomes an Act the water companies shall prepare and submit to the Local Government Board a statement describing the work which they propose to undertake for the improvement of intercommunication of mains. The Local Government Board are to have the power to direct inquiries with regard to the matters affecting intercommunication of the mains and are to possess the powers identical with those which they now have under the Public Health Act, 1875. The expenses of such inquiries are to be paid by the metropolitan water companies. The companies are to have power to lay new mains in the streets and to do any work necessary for that purpose in streets, bridges, &c., not only within their own limits of supply but within the limits of the statutory area of supply of any other of the metropolitan companies by permission of that company. In the case of drought any metropolitan company is to allow passage of water through their mains for the use of a company requiring an extra supply, but the mains are not to be so used to the prejudice of the arrangements for the supply of the customers of the company through whose mains the water is to pass.

The Local Government Board are to have power to authorise or require companies to abstract from the Thames or its tributaries an additional amount of water should occasion require The Local Government Board are to have power to require any company to increase their pumping power and to enforce orders and regulations to ensure the carrying out of these provisions The Board are also to have power to attach penalties for the omission of such orders and regulations, to recover them in a summary manner, and to apply them in any way they may direct. The metropolitan companies are to have power to acquire land and easements for carrying out the provisions of the Act An arbitrator is to be appointed within three months of the passing of the Act by the companies or, should they fail to agree by the Local Government Board The arbitrator so appointed is to hold his office for some period not greater than three years His remuneration is to be settled by the water companies or, should they fail to agree by the Local Government Board and he is to be paid by the water companies or some of them as they may agree in such proportion as the companies may from time to time agree upon or, should they not agree as the arbitrator himself may appoint An important clause relates to the retrospective action of the Act It is provided under Section 13 that—

---

[1] THE LANCET, Jan. 28th, p. 245.

[2] A Bill for Improving and Facilitating Intercommunication between the Mains and Works of the Metropolitan Water Companies.

> 13. Anything done by any one or more of the metropolitan water companies before the passing of this Act which would have been valid and within their respective powers if this Act had been passed in the *session of Parliament holden in the year one thousand eight hundred* and ninety-eight and the expenditure of money by such company or companies in reference thereto is hereby sanctioned and confirmed.

The companies are to be allowed to raise money on debenture for the purposes of carrying out the Act New debenture stocks are to be offered by auction or tender, the purchase money of the capital sold by auction is to be paid within three months Notice is to be given to certain officials as to the sale of the shares The officials to be notified are the clerk of the London County Council, the town clerk of the City of London, the secretary of the London Stock Exchange, and the clerks of the various county councils who might be affected, and in the case of the East London Company the clerk of the Borough of West Ham The stock which is not sold by auction or tender is to be offered to shareholders Should there be a premium arising from the stock it is to be applied for the purposes of the Act The amount of stock is limited to £600 000 Certain provisions are made between the companies as to the payment of interest of debenture stock

MEDICAL QUALIFICATIONS IN FRANCE AND THE POSITION OF THE ALIEN MEDICAL MAN

IN our issue of Dec 10th 1898 we published a communication from our Paris correspondent upon the above important subject In this our correspondent was made to say "The *diplome d Université* does not authorise the holder to practise outside France herself . Foreigners who wished to practise in France were allowed to do so as before under easy conditions but they were only to receive the *diplome d Université* This statement of course implied that foreigners could practise in France with the *diplome d Université* This, however is not correct and we regret that owing to an error, and one which in justice to our Paris correspondent we wish to say was in no way due to him the statement should have appeared in our columns Our attention was called to the matter by a correspondent and we submitted his statement to our Paris correspondent who has sent us the following ' The *diplome d' Université* granted by the faculty of Paris gives no right to practise in France The medical study for it is the same as for the other diploma, but greater facilities are granted to foreigners for obtaining it and studies already gone through in their own countries are allowed to count The *diplome d état* alone gives the right to practise in France or her colonies and to obtain it the student before commencing his medical studies must undergo in France the examination for the *baccalauréat* (*bachelier de l enseignement secondaire classique*) and a preliminary examination in physics chemistry and natural science No remission of the preliminary examination is granted to any one, be he Frenchman or foreigner

THE ARMY MEDICAL SCHOOL, NETLEY.

THE winter session of 1898-99 was brought to a close on Jan 31st, when the results of the recent examination were announced and the prizes were distributed by Sir Ralph Knox, K C B , *Permanent Under Secretary of State for War*, in the presence of Surgeon General Jameson, C B , Director-General, A M S Lieutenant General Sir Baker Russell K C B , commanding the Southern District Surgeon General Cuffe, C B , P M O of Portsmouth, the military staff of the Royal Victoria Hospital, Netley, and a distinguished company of visitors

Colonel NOTTER, Professor of Hygiene, announced the results reporting that the work of the session had been satisfactory, that the whole of the 50 surgeons on probation who had undergone the final examination had proved themselves fitted to receive Her Majesty s commission that in general ability they were of fair average, and that their conduct while passing through the school had been excellent

The subjoined lists show the final positions of the officers with the marks which they obtained at the examinations and *the prizes gained at the Army Medical School*

SIR RALPH KNOX after distributing the prizes and saying a few words to each prize winner, especially to Mr Harvey who entered the Army Medical School by nomination and who, he said, by his diligence had shown that nomination had proved a success, addressed the young officers in a speech of which the following is an abstract He said he feared that his selection for the performance of the function was not peculiarly happy, for though for many years he had known much about army medical officers he had to confess that most of his thoughts were directed to ascertaining how few of them would suffice for their work and what was the minimum remuneration which would induce them to join the service He however, could say that his interest in the service had been very great and *that he had served* on many committees dealing with important questions connected with their *duties* Now, he had to *give them a word* of encouragement on starting on their career in life He *first congratulated* them on at last having completed that terrible examination period of life through which it appeared that all young men nowadays had to pass and he was very pleased to hear that the standard of their work was so high and the general results so satisfactory and he thought that they might look forward with confidence to their lives as members of the noblest and most continuously self-sacrificing of all professions. They must have high ideals, for a member of their service was both surgeon and soldier too. The firing of guns and rifles imposed no specially arduous task on anyone. What called for the display of all the finest soldierly qualities was the performance of these duties under fire; and it could not be said nowadays that anyone associated with the combatant army anywhere near the front was not within the zone of fire of the long range of the present field guns or that of the low-trajectory rifle. Doubtless there were men of various abilities in the class; some who had had good luck and some whose luck was bad, but with whatever ability they were equipped now that they were becoming members of the great social organism there were two qualities they should possess in order to secure success—namely, tact and courtesy—or in more homely phrase common-sense and good manners. Without these the best abilities often failed of success, and with them the deficient talent was often compensated. He would urge them to continue their reading not merely of technical works but of the best literature of their country; they should check in some way the narrowing influences of a special service. They should practise putting down their thoughts, whether technical as derived from their work or not, in writing. It was Bacon who said, "Reading maketh a full man, writing an exact man," and a medical officer in the army should be both; and the third of the three R's should not be neglected. It was most useful to cultivate arithmetical thought; they had doubtless learned something about statistics. These could not be properly prepared by anyone who did not accurately perceive the limited sense in which a fact could be stated in figures, and as army statistics afforded the information on which many all-important decisions depended he urged the careful preparation of the returns which they would be called upon to render. He feared that the remarks he had made were somewhat trite, but they contained such advice as he would give to his own son, and the short intercourse he had had with the young officers, especially the very agreeable and joyous evening of the day before, had led him to regard them as special boys of his own, whose names he now possessed, and whose careers in the future he would be always interested in. He congratulated them very sincerely and on behalf of all present offered them the heartiest good wishes for their future.

The DIRECTOR-GENERAL, after thanking Sir Ralph Knox for his able speech and for his kindness in coming to Netley, remarked that the young officers of the Indian Medical Service were sure to find interesting work in India and opportunities of distinction, for plague, pestilence, famine, and war were one or all of them nearly always present in the country they were going to. He congratulated them on obtaining their commissions. Turning to the young officers of the Royal Army Medical Corps he said that they were entering the service with a fair wind and that this was so was due to the wise policy of Lord Lansdowne who had given them the warrant which they so highly valued and whose name would in the future be ranked with that of Lord Herbert of Lea as one of the greatest benefactors of the medical service of the army. Associated with Lord Lansdowne in drawing up the recent warrant had been Sir Ralph Knox and his predecessor, Lord Haliburton, in both of whom the medical officers of the army had found firm and excellent friends.

The proceedings were brought to a termination by a few words addressed to the young officers by Surgeon-General NASH who wished them God-speed in their careers. The company was subsequently entertained at luncheon by Surgeon-General Nash and the officers of the Royal Army Medical Corps.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE forty-eighth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Jan. 31st. The Commissioners present were the Chairman (Lord Llandaff), the Right Hon. John Mellor, Sir John Dorington, Sir George Barclay Bruce, Mr. de Bock Porter, Mr. Lewis, and Major-General Scott. The witnesses examined were Lieutenant-Colonel Mark Lockwood, M.P., and Mr. William Booth Bryan, the chairman of, and engineer to, the East London Waterworks Company.

Mr. BRYAN put in a statement as to their sources of supply and a brief description of the works of the company, a table giving a description of the engines and the capacity of the pumps at the various stations of the company, and a table showing the distribution of the capital expenditure of the company from the year 1880 to the year 1896. A description of the company's works has already been fully given in THE LANCET.[1] Mr. Bryan gives in a footnote to his tables some information as to the time during which pipes last. Mains have been dug up and found to be in a perfectly good condition after having been in the earth for upwards of 60 years. The chief accidents which occur to pipes are those produced by the effects of frost and it is found also that in some districts in which the ground has been artificially made up the mains have been injuriously affected by the local conditions. Apart from such accidents no period can be assigned as the proper "life of a main."

Colonel LOCKWOOD was cross-examined by Mr. BALFOUR BROWNE on behalf of the London County Council. Mr. Balfour Browne pointed out that Mr. Charles Greaves (a former engineer to the East London Company), in giving evidence on a Bill which was before Parliament in the year 1867, said that in the year 1864 they had found that the supply of water from the Lee was barely sufficient for their requirements. In that year there was "the greatest drought within the memory of any one." The company resolved to make application to Parliament for powers to take a supply from the Thames and to increase their storage capacity at Walthamstow. In 1867 before the Royal Commissioners on the Water-supply Mr. Greaves gave evidence to the effect that he thought that the company ought not to be entirely dependent on the Lee. He was of opinion that the Lee alone could not be depended upon for the supply of East London and he proposed to combine the Thames works and the Lee works and to use the reservoirs in the Lee Valley for the storage of Thames water should occasion require.

In answer to Mr. BALFOUR BROWNE the witness said that the East London Company were taking steps to obviate a water famine in the future and that the new work would involve a large expenditure. The works in contemplation provided for the supply of an increased population. With regard to the question of control the witness said that he would be willing that the water examiner appointed by the Local Government Board and the analyst should be admitted to the works of the company. He thought that the more publicity there was with regard to the companies' works the better it would be. The analyst, had, of course, access to the taps in East London, but the witness thought that he ought also to have a right to visit the works of the company. If the undertaking were bought by the London County Council that body might obtain profits on any new works which might be made for an increased population.

Major-General SCOTT pointed out that they would also have to take the risks.

Mr. BRYAN explained the conditions on which the East London Company takes water from the Lee and the way in which water is pumped up to the lower reaches of the Lee Navigation Canal during periods of drought.

The CHAIRMAN said that they had heard something about the pumping of polluted water from the lower reaches to the higher reaches. The witness explained that the company had a pumping station at Bromley Lock. At this point the tide passes through at high water and enters the Navigation Canal. The tide flows up as far as Old Ford Lock, at which place the upper pond is about eight feet higher than the lower and the tide can get no higher up the Navigation Cut. The tidal water, however, can pass round through "back rivers" higher up. The Lee Navigation is canalised and the tide can get no further than Old Ford. Barges go up the Lee Navigation through the artificial canal. They also go up certain "back rivers" to Stratford. The vessels go to Old Ford on the tide and there are gates which open with the tide at Bromley Lock. The barges come into the Navigation Canal on the tide and the gates are closed as soon as the tide begins to ebb. The traffic into the Thames then depletes or lowers the head of water in the Limehouse Cut. At this point the East London Company have put up a pumping station to raise water from the low level as the tide is rising in order to keep up the Navigation water to its proper head and to make up the loss caused by the lockage of barges going out into the Thames. The amount of water which the Conservators of the Lee have a right to take for the purposes of navigation is 5,400,000 gallons daily. This amount is made up partly by water pumped by the East London Company in the manner mentioned and partly by water which flows down the Lee Navigation. By pumping up the tidal water the company are enabled to take more water for the supply of their customers.

---

[1] THE LANCET, May 1st, 8th, 15th, 22nd, and 29th, 1897.

Mr. DE BOCK PORTER asked whether the Lee Conservancy Board acquiesced in this arrangement. The witness replied that it was a statutory arrangement and that in the Act of Parliament there was a clause which enabled the company to pump from pound to pound and to provide part of the statutory quantity by this means.

In answer to Sir JOHN DORINGTON, the witness said that the company put up temporary pumps to raise the water from one pond to another. The water is pumped up beyond Tottenham Lock but never into the reach which supplies water from the intake of the company.

In answer to Sir JOHN DORINGTON the witness said that the water of the Lee runs down the Navigation and is not under the control of the East London Company.

The witness explained to the Commissioners exactly how the water was pumped and pointed out on a map the situation of the various places to which he referred. Briefly the evidence amounted to this: The East London Company pump from the old tidal channel of the river Lee into the Lee Navigation at Bromley Lock; they occasionally pump at Old Ford Lock which is slightly higher up the Navigation channel. This water flows into the Bottom Pound Lock and the reach into which the water is pumped is four miles in length and extends to Tottenham. Above Tottenham water is pumped into the Navigation channel. The water so pumped does not go beyond Stone Bridge Lock. No brackish water is pumped to any place through which it could pass to the intake of the company near Enfield Mill. The pumping station near Bromley Lock is a permanent station; at other places the pumping is effected by portable engines.

In answer to the CHAIRMAN the witness said that during the water famine of last year there was a great deal of wilful waste and the company received a large number of letters from their customers calling attention to the waste in different places and asking them to put a stop to it. On the other hand, the company received letters from people saying that they would allow the water to run away in order "to spite them."

The CHAIRMAN said that this was a serious statement and Mr. PEMBER suggested that the letters should be produced. The witness said he had none with him but that they could be produced.

Sir JOHN DORINGTON asked the witness whether he agreed with Sir Alexander Binnie's inference that powers granted by corporations could not safely be given to water companies with regard to measures for the prevention of waste of water, and with regard to powers for testing the fittings which were used by the water consumers The witness said that in one of their bills they had inserted clauses copied from the Manchester Corporation Waterworks Acts which dealt with these matters. The local authorities in whose districts the company gave their supply strongly objected to this supervision and the clause was therefore withdrawn.

In answer to Sir JOHN DORINGTON the witness said that the local authorities thought that the company was trying to get too much power into their own hands. He did not know, however, whether the local authorities themselves would have been inclined themselves to exercise such powers on behalf of the company had they been entrusted to them.

In answer to Mr. FREEMAN, who cross-examined on behalf of the London County Council, the witness said that the Lee Conservators had power over the water of the river and took what they wanted. He could not say what amount of water was actually taken by the Conservators for the purposes of navigation. He was unable to say how much was pumped up into the lower reaches of the river. The pumps used were centrifugal pumps and it was not possible to estimate what the amount pumped actually was. The Navigation water was kept up to its proper level and the pumping arrangements were made to effect this. When the right height of water was obtained pumping operations ceased.

Lord ROBERT CECIL cross-examined on behalf of the Hertfordshire County Council, and asked some questions about the wells.

The CHAIRMAN said that the Commissioners had "nothing to do with deciding whether or not the New River Company and the East London Company are injuring wells and springs in Hertfordshire."

Lord ROBERT CECIL contended that the case for Hertfordshire was that the supply in that county had already been drawn upon more than the supplies from the heavens warranted. If the chairman told him that the Commission would safeguard the interests of Hertfordshire he would not wish to examine further.

The CHAIRMAN said: We have nothing to do with the interests of Hertfordshire, you must take care of yourselves.

Lord ROBERT CECIL said: It is very material to Hertfordshire and it is very material for the supply of water to London.

The CHAIRMAN said: We are not inquiring into the supply of water to London but into the expediency of transferring the supply of water to London from the companies to a purchaser.

The forty-ninth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Feb. 6th. The Chairman (Lord Llandaff) and all the Commissioners were present. The witnesses examined were Mr. Isaac A. Crookenden, secretary of the East London Waterworks Company, and Sir Henry Knight, chairman of the Southwark and Vauxhall Company. Supplemental papers referring to the East London Waterworks Company's financial state were put in. Sir Henry Knight put in tables referring to the financial state of the Southwark and Vauxhall Company.

At the commencement of the proceedings Mr. PEMBER, Q.C., on behalf of the East London Company, made a statement with regard to the statistics which had been put in referring to the probable increase in the population of the district within the company's area of supply. Three different estimates had been made. Lord Balfour's Commission had suggested that the decennial increase of the district would be 25 8 per cent., and if this proved correct in the year 1937 the population would amount to 3,165,445. At an average daily supply per individual of 35 gallons, 110,790,000 gallons of water a day would be required and the cost of the work necessary to carry out this was estimated at £4,238,000. The directors of the East London Company, however, found that the increase of the population had been 17·1 between the years 1886 and 1896, and they therefore thought that the estimates made by the Balfour Commission were in excess of the amount of population which they would probably be called upon to supply.

Mr. CROOKENDEN, in answer to the CHAIRMAN, explained how the estimate of a decennial increase had been obtained and, in answer to further questions, said that between the years 1891 and 1898 the population had increased at the rate of 22 65 per cent.

The CHAIRMAN pointed out that as the average increase of the population of the East London Company's area had been higher than the average of 18 2, which was the estimate given by Lord Balfour's Commission for the whole of London, it did not seem safe to take that average as a basis for future calculations of the East London Company's district.

Mr. BALFOUR BROWNE cross-examined the witness with regard to the profits made by the company immediately before the water famine of last year and asked for an explanation of how it was that the expenses had been reduced and the profits at the same time increased. The witness pointed out that the expenses of 1896 were larger than those of 1897, because in the former year a considerable outlay had been caused by repairing the damage done by the frost of the year 1895.

The witness gave some particulars with regard to the profits recently made by the East London Company. He had not come with the figures worked out and as Mr. Pember on behalf of the East London Company had to correct the figures at a subsequent meeting of the Royal Commissioners it is useless to publish them. [Mr. Pember explained at the fiftieth sitting held on Feb. 7th, that Mr. Crookenden was unwell when he gave his evidence.]

Mr. BALFOUR BROWNE asked the Chairman to what decision the Commissioners had come with regard to addresses by counsel at the conclusion of their reception of evidence. He contended that the counsel for the companies should first address the Commissioners and that he should have the final right to reply.

Mr. LITTLER, Q.C., and Mr. PEMBER, Q.C., on behalf of the water companies, strongly objected to this method of procedure and the CHAIRMAN remarked that the Commissioners might possibly be driven to exercise their prerogative and not hear counsel at all.

Mr. PEMBER expressed a hope that counsel would be allowed to speak. Mr. BALFOUR BROWNE was content to leave the evidence in the hands of the Commissioners.

The CHAIRMAN said that he was unable to decide from the evidence whether the London County Council were desirous that the Commissioners should advise purchase on the ordinary terms of arbitration or whether they wished the Commissioners to find that purchase would be expedient only on certain special terms. In this condition of uncertainty it would, he said, be more convenient had the representatives of the London County Council spoken first, but as they claimed to be heard last as a matter of right on the analogy of Parliamentary committees the Commissioners had decided that the London County Council had such a right and it would therefore be necessary for the counsel representing the water companies to give their arguments in what he termed alternative form, forecasting as best they could the views which the London County Council might represent. The Chairman added that the question as to who spoke first or last would not in any way influence the Commissioners.

Mr. BALFOUR BROWNE said that he thought the question as to whether the London County Council wished to buy the companies only on the condition of obtaining special terms should be referred to his clients and that he would make a statement upon the subject before counsel for the water companies made their speeches.

Sir HENRY KNIGHT, chairman of the Southwark and Vauxhall Company, took a cheerful view of the company in which he was interested. Their maximum dividend of 10 per cent., he thought, was "immediately in sight." He did not think that the purchase of the water companies would be an advantage to the water consumers of London, because under the sinking fund clauses which were now in force when further capital was raised by the companies the people of London would ultimately become possessed of all the undertakings without paying for them.

In answer to the CHAIRMAN who asked whether it would take one, two, or three centuries to accomplish this object the witness said that he had not made any calculation. He gave it as his opinion that an equalisation of the water rents throughout London would be unfair to the poorer customers, and he further gave it as his opinion that he thought it right that notwithstanding the failure to give a constant supply by the East London Company that company ought not to suffer financially for their default.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Derbyshire County District.—The annual report for 1897 on the health of this district has but recently reached us, and at a time when the reports for 1898 are making their appearance. This delay in the issue of reports is distinctly to be regretted and we think that all medical officers of health of whatever standing should use every effort to expedite the issue of their reports. The estimated population of Derbyshire at the middle of 1897 was 474,015—i.e., rather less than the population of Birmingham at the last census. The county birth-rate was 32·67 and the general death-rate was 16·27 per 1000. As regards infectious diseases we note that the death-rate from enteric fever for 1897 is considerably in excess of that of England and Wales, the chief cause of this prevalence being regarded as polluted soil, and Dr. Sidney Barwise in his report strongly urges the abolition of privies and the substitution of the water-carriage system. In the matter of tuberculosis an example has been set to the county by the late Lord Vernon who remodelled two farms in such a manner that each cow has 800 cubic feet of air space and proper regard is paid to warming and ventilati As a result of the tuberculin test no less than 54 per cent. the cows on the estate were found to be tuberculous. Th latter were isolated and fed up for slaughter whilst remainder were very wisely removed to new cowshe Each farm is furnished with a refrigerator and a centrifu machine through which the milk is passed after milki It is then by means of machinery which dispenses with manipulation decanted into bottles and heated up to 186 After being suddenly cooled and left for two hours with object of allowing the conversion of spores into bac the milk is completely sterilised by being heated for minutes at a temperature of 212° F. The bottles are th hermetically closed automatically and rapidly cooled. cordially endorse Dr. Barwise's hope "that the increas price which the milk realises will be sufficient to indu other landowners to follow the example set by Lord Verno

Maldon Rural District.—As usual, Dr. Thresh is settin good example by the early issue of his annual report for 18 on the sanitary condition of this district. The drought last summer has not been an unmixed evil as it has broug home to the inhabitants of certain parts of this district wh it means to have their springs dried up during the hot weath They are now adopting a different attitude towards I Thresh's schemes for water-supply than was formerly the ca Complaints are still heard in this district as to the nuisan caused by the unloading and carting of London manure a it is satisfactory to hear that henceforth the business will duly regulated by by-laws drawn up for the purpo The "Peculiar People" have not yet ceased to be pecul in the sense that they decline to seek medical advice in ca of illness, and hence infectious disease amongst them is n brought to light. It was, however, recently decided in t High Court that failure to seek medical assistance co stitutes "neglect" in the eyes of the law and Dr. Thre trusts that there may be relief from the present unsat factory state of affairs under this decision. By way assistance to medical men in the diagnosis of phthi Dr. Thresh in his capacity of county medical officer of heal undertakes the bacteriological examination of sputum at l laboratory. For poor patients the charge is *nil*; for othe a nominal fee of 2*s.* 6*d.* is charged. Dr. Thresh apparent looks to educational rather than to legislative measures diminish the death-rate from tuberculous disease.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6717 births ar 4275 deaths were registered during the week endin Feb. 4th. The annual rate of mortality in these town which had declined in the four preceding weeks from 19 to 17·0 per 1000, rose again last week to 19·5. London the rate was 19·4 per 1000, while it averag 19·7 in the 32 provincial towns. The lowest death-rat in these towns were 11·0 in Croydon, 13·1 in Brighto and in Huddersfield, 14·3 in Norwich, and 14·5 in Hull; th highest rates were 23·5 in Newcastle-upon-Tyne, 24·5 Gateshead, 25·2 in Liverpool, and 27·2 in Sunderland. Th 4275 deaths in these towns included 340 which were referr to the principal zymotic diseases, against 380 and 329 the two preceding weeks; of these, 98 resulted from whoo ing-cough, 87 from diphtheria, 64 from measles, 34 fro "fever" (principally enteric), 31 from scarlet feve and 26 from diarrhœa. No death from any of the diseases was recorded last week in Norwich; in the oth towns they caused the lowest death-rates in Croydo Brighton, Birkenhead, and Newcastle-upon-Tyne, and th highest rates in Preston, West Ham, Sheffield, and Bolto The greatest mortality from measles occurred in Ma chester, Oldham, and Bolton; and from whooping-cough Bristol, Swansea, Nottingham, Preston, Halifax, and Gate head. The mortality from scarlet fever and from "fever showed no marked excess in any of the large towns. Th 87 deaths from diphtheria included 32 in London, nine Leeds, eight in Sheffield, six in West Ham, five Birmingham, five in Leicester, five in Liverpool, and thr in Portsmouth. No fatal case of small-pox was register last week in any of the 33 large towns, and no smal pox patients were under treatment in any of the Metr politan Asylums Hospitals. The number of scarlet fev patients in these hospitals and in the London Fev

* Including 32 cases of membranous croup.

† Including deaths from membranous croup.

Hospital on Saturday last, Feb. 4th, was 2665, against numbers declining from 2939 to 2679 at the end of the five preceding weeks; 265 new cases were admitted during last week, against 220, 249, and 220 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 295 and 266 in the two preceding weeks, rose again last week to 348, but were 136 below the average. The causes of 70, or 1·6 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Salford, Oldham, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, Preston, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·3 and 22·1 per 1000 in the two preceding weeks, further rose to 28·4 during the week ending Feb. 4th, and exceeded by as much as 8·9 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 16·9 in Perth and 19·7 in Dundee to 32·5 in Greenock and 33·2 in Glasgow. The 866 deaths in these towns included 43 from whooping-cough, 20 from diarrhœa, 16 from measles, seven from scarlet fever, seven from diphtheria, and two from "fever." In all, 95 deaths resulted from these principal zymotic diseases, against 94 and 78 in the two preceding weeks. These 95 deaths were equal to an annual rate of 3·1 per 1000, which was 1·5 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough which had declined from 35 to 30 in the three preceding weeks, rose again to 43 last week, of which 25 occurred in Glasgow, 11 in Edinburgh, and three in Leith. The 16 deaths referred to measles exceeded by one the number in the preceding week, and included nine in Aberdeen and six in Edinburgh. The fatal cases of scarlet fever, which had been six and 14 in the two preceding weeks, declined again to seven last week, of which five occurred in Glasgow and two in Edinburgh. The deaths from diphtheria which had been nine in each of the two preceding weeks declined to seven last week, and included three in Glasgow and two in Aberdeen. The two fatal cases of "fever" were recorded in Aberdeen. The deaths referred to diseases of the respiratory organs in these towns, which had been 153 and 161 in the two preceding weeks, further rose to 282 last week, and were 165 above the number in the corresponding period of last year. The causes of 52, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·6 and 24·9 per 1000 in the two preceding weeks, rose again to 31·8 during the week ending Feb. 4th. During the past four weeks the death-rate in the city has averaged 28·1 per 1000, the rate during the same period being 17·6 in London and 24·2 in Edinburgh. The 213 deaths registered in Dublin during the week under notice showed an increase of 46 upon the number in the previous week, and included 10 which were referred to the principal zymotic diseases, against 10 and 11 in the two preceding weeks; of these, four resulted from diarrhœa, three from whooping-cough, two from scarlet fever, one from "fever," and not one either from small-pox, measles, or diphtheria. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·5 in London and 4·0 in Edinburgh. The fatal cases of whooping-cough, which had increased from three to five in the three preceding weeks, declined again to three last week. The two deaths referred to scarlet fever exceeded the number recorded in any recent week; while the mortality from whooping-cough showed a marked decline from that recorded in recent weeks. The 213 deaths in Dublin last week included 40 of infants under one year of age and 65 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons considerably exceeded the numbers registered in any recent week. Eight inquest cases and five deaths from violence were registered; and 67, or nearly a third, of the deaths occurred in public institutions. The causes of 25, or nearly 12 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JANUARY, 1899.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during January in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 9·2 per 1000 of the population, estimated at 4,546,752 persons in the middle of this year. In the three preceding months the rates had been 11·5, 10·8, and 9·5 per 1000 respectively. The rates were considerably below the average in Westminster, Hampstead, St. Giles, St. Martin-in-the-Fields, Strand, and St. Olave Southwark; while they showed the largest excess in Fulham, City of London, St. Saviour Southwark, Newington, Battersea, Wandsworth, Greenwich, Woolwich, and Plumstead sanitary areas. Only two cases of small-pox were notified in London during January (one in Greenwich and one in the Port of London), and only one small-pox patient was under treatment last month in the Metropolitan Asylums Hospitals. The prevalence of scarlet fever in London showed a slight increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Bermondsey, Rotherhithe, Wandsworth, Greenwich, Woolwich, Lee, and Plumstead. The Metropolitan Asylums Hospitals contained 2637 scarlet fever patients at the end of January, against 2977, 3090, and 2883 at the end of the three preceding months; the weekly admissions averaged 239, against 350, 288, and 239 in the three preceding months. The prevalence of diphtheria in London during January showed a slight further decline from that recorded in recent months; this disease was proportionally most prevalent in Fulham, Limehouse, St. Saviour Southwark, St. George Southwark, Newington, Battersea, and Plumstead sanitary areas. There were 1358 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of January, against 1182, 1269, and 1239 at the end of the three preceding months; the weekly admissions averaged 166, against 172 and 173 in the two preceding months. The prevalence of enteric fever in London showed a further marked decline from that recorded in the two preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in St. James Westminster, Holborn, St. Luke, London City, Limehouse, Poplar, and Rotherhithe. The Metropolitan Asylums Hospitals contained 249 enteric fever patients at the end of January, against 223, 286, and 255 at the end of the three preceding months; the weekly admissions averaged 34, against 41, 45, and 36 in the three preceding months. Erysipelas was proportionally most prevalent in St. George Hanover-square, Bethnal Green, Limehouse. St. Saviour Southwark, Newington, and Greenwich sanitary areas. The 25 cases of puerperal fever notified in London during January included five in Lambeth, two in Bethnal Green, two in Wandsworth, and two in Lewisham sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Jan. 28th, the deaths of 5946 persons belonging to London were registered, equal to an annual rate of 17·0 per 1000, against 17·3, 16·3, and 16·9 in the three preceding months. The lowest death-rates in the various sanitary areas were 9·7 in Lee, 10·1 in Hampstead, 11·1 in Stoke Newington, 13·0 in Plumstead, 13·4 in Wandsworth, 13·8 in Hackney and in Lewisham, and 14·1 in Fulham; the highest rates were 21·9 in City of London, 22·3 in Whitechapel, 23·0 in St. George Southwark, 23·6 in St. George-in-the-East, 23·8 in Holborn, 24·8 in St. Saviour Southwark, 25·2 in St. Luke, and 25·7 in Newington. During the four weeks of January 520 deaths were referred to the principal zymotic diseases in London; of these, 105 resulted from measles, 39 from scarlet fever, 125 from diphtheria, 154 from whooping-cough, 55 from enteric fever, and 42 from diarrhœa, but not one either from small-pox, typhus, or any ill-defined form of continued fever. These 520 deaths were equal to an annual rate of 1·5 per 1000, against 1·5 and 1·7 in the two preceding months. No death from any of these zymotic diseases was recorded last month in Strand or in St. Olave Southwark; in the other sanitary areas they caused the lowest death-rates in St. George Hanover-square, Westminster, Hampstead, Stoke Newington, St. Giles, City of London, and Lee; and the highest rates in Chelsea, St. Pancras, Shoreditch, Bethnal Green, Whitechapel, Mile End Old Town, St. Saviour Southwark, and Newington. The 105 fatal cases of measles were as many as 157 below the corrected average number in the corresponding periods of the 10 preceding years; this disease showed the highest proportional fatality in Clerkenwell, Shoreditch, Bethnal Green, Whitechapel, Mile End Old Town, and Newington sanitary areas. The 39 deaths referred to scarlet fever were just half the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Fulham, Rotherhithe, and Plumstead. The 125 fatal cases of diphtheria were 44 below the corrected average number; this disease showed the highest proportional fatality in Chelsea, Holborn, Shoreditch, Whitechapel, Mile End Old Town, St. Saviour Southwark, Newington, and Bermondsey sanitary areas. The 154 deaths from whooping-cough were 125 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Paddington, Chelsea, St. George Southwark, and Newington. The 55 fatal cases of enteric fever were 11 above the corrected average number; this disease showed the highest proportional fatality in St. James Westminster, Clerkenwell, St. Luke, Bethnal Green, and St. George-in-the-East sanitary areas. The 42 deaths from diarrhœa were 13 below the average. In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was more than 41 per cent. below the average.

Infant mortality in London during January, measured by the proportion of deaths of children under one year of age to registered births, was equal to 112 per 1000, and was considerably below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. James Westminster, Stoke Newington, Newington, Clerkenwell, St. Olave Southwark, Woolwich and Lee; and the highest rates in Chelsea, St. Martin-in-the-Fields, Strand, Holborn, St. Saviour Southwark, and Newington.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Staff Surgeons: E. J. Biden to the *Orlando*; W. M. Lory to the *Aurora*; E. C. Ward to the *Penguin*; and B. O. E. F. Gunn to the *Repulse*. Surgeons: E. S. Reid to the *Orlando*; E. F. Power to the *Aurora*; R. St. G. S. Bond to the *Collingwood*; G. Hewlett to the *Comus*; A. W. Campbell to the *Royal Arthur*; and T. Austen to the *Wildfire* for Sheerness Yard.

ROYAL ARMY MEDICAL CORPS.

Major R. Kirkpatrick proceeds to Fort George for duty, vice Lieutenant J. S Gallie, who has been ordered to Maryhill. Major M. W. H. Russell is posted to the Western Heights, Dover, for duty. Captain H. J. M. Buist joins at Woolwich. Captain J. H. Rivers, in medical charge, Station Hospital, Purandhar, will, on his departure to Cairo for service with the Egyptian Army, be relieved by Lieutenant A. H. Morris.

Captain Julian P. S. Hayes to be Major and Captain Robert Caldwell to be Major The under-mentioned Lieutenants to be Captains: Frederick S Brereton, John C. B. Statham, Robert M. Le H. Cooper, Edwin C. Hayes, Percy J. Probyn, Anthony H. Waring, Arthur W. Hooper, William A. Ward, and Edmund G. Forrest.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Alic Phillips, the Manchester Companies, Volunteer Medical Staff Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 4th Durham (Western Division, Royal Artillery): Robert Hanton to be Surgeon-Lieutenant. 1st Midlothian: William Macrae Taylor to be Surgeon-Lieutenant. *Rifle*: 1st Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Lieutenant A. R. Stoddart to be Surgeon-Captain. 1st Volunteer Battalion, the Lancashire Fusiliers: Surgeon-Lieutenant A. P. Nuttall to be Surgeon-Captain. 4th Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant E. J. Weightman resigns his commission. 24th Middlesex: Surgeon-Lieutenant C. R. Handfield-Jones to be Surgeon-Captain. 1st Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): William Norman Evans to be Surgeon-Lieutenant. 13th Middlesex (Queen's Westminster): Charles Arthur Morris to be Surgeon-Lieutenant. 2nd Volunteer Battalion, the Highland Light Infantry: Archibald Neville McLellan, to be Surgeon-Lieutenant. 9th Lanarkshire: James Craik Taylor to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Surgeon-Captain F. J. L. Warwick, from the 1st Tower Hamlets Volunteer Rifle Corps, to be Surgeon-Captain.

VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force:—*North-Eastern District*: *Rifle*: 1st Volunteer Battalion the Northumberland Fusiliers: Surgeon-Captain John Peter Elliot. 2nd Volunteer Battalion the Northumberland Fusiliers: Surgeon-Lieutenant-Colonel Hugh Frazer Hurst, retired. *Scottish District*: *Rifle*: 8th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant-Colonel John Stewart Muir. *Southern District*: *Rifle*: 3rd (Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment: Surgeon-Major Charles Knott. *Western District*: *Rifle*: 3rd Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant-Colonel Evan Jones.

THE FIGHTING AT MANILA.

The rapid current of events has compelled the Americans to "take up the white man's burden" and face the consequences of the obligations and responsibilities which they have incurred by their war with Spain. That the United States will manfully accept the position caused by the abolition of Spanish rule and influence does not admit of doubt, especially now that the boldness of the Filipino insurgents has by challenging the military and naval forces at Manila thrust this duty upon the American Government. From the information which has already been published it is clear that the recent fighting at Manila was of a severe character; that the American troops behaved with their accustomed gallantry; and that the insurgents were badly defeated and driven back with a very considerable loss. The fighting took place last Saturday and Sunday and was on an extended scale After a fierce encounter the Californian Regiment drove the rebels out of their stronghold at Paco. It is estimated that the insurgent losses amounted to 4000 killed and wounded and that the casualties on the American side were about 175, of whom 40 were killed. The total American force in and around Manila amounts to 15,000 or 20,000 men. Of this number it is reported that some 2500 are in hospital suffering from typhoid fever, small-pox, dysentery, and other diseases incidental to service in that climate. It is said that many soldiers of the American Volunteer force, unused to all the discomforts of field service, are sick of the war and longing to return to their homes. Strong reinforcements are on their way from the States and although the task of reducing the insurgent native population to law and order may prove a longer and more difficult task than was anticipated there is no doubt whatever that it must and will be accomplished.

THE HEALTH OF THE NAVY.

The returns of 1897 for the total force serving afloat may be regarded on the whole as very satisfactory. The death-rate of the total force—viz., 5·23 per 1000—is 0·05 less than that of the previous year, and 1·62 below the ten years' average. It is also the lowest recorded since 1856. The invaliding rate, however, shows an increase of 1·62 per 1000 over that of 1896 and of 5·44 when compared with the average ratio for the last ten years. Four cases of yellow fever are reported from the North American and West India Station, resulting in one invaliding and in three deaths. No case of bubonic plague is returned. There has been a considerable increase in the number of cases of enteric fever on the Mediterranean Station, chiefly contributed to by an outbreak of the disease which occurred on board the *Forte* at Phalerum Bay. The ratio per 1000 of cases of primary and constitutional syphilis shows a slight increase when compared with 1896. Contrasted with the average ratios of the last ten years there is an increase in the latter but a decrease in the former of 5·39 per 1000, and a slight decrease is also apparent in those of gonorrhœa and its sequelæ. The total force in the service afloat, corrected for time, in the year 1897, was 80,540 officers and men, of whom 47,720, or 59·25 per cent., were between the ages of 15 years and 25 years; 23,740, or 29·47 per cent., were between the ages of 25 years and 35 years; 7650, or 9·49 per cent., were between the ages of 35 years and 45 years; and 1430, or 1·77 per cent., were 45 years of age and upwards. The total number of cases of disease and injury entered on the sick-list was 72,068, which is in the ratio of 894·81 per 1000, being a decrease, compared with the previous year, of 16·26 per 1000, and of 71·32 per 1000 when compared with the average ratio of the last ten years.

THE RUSSIAN GARRISON AT PORT ARTHUR.

It is reported that information has reached the Russian War Office of the grave prevalence of sickness, attended with much mortality, among the Russo-Chinese force at Port Arthur. During November and December last, the correspondent of the *Standard* states, there were 215 deaths and the average mortality was at the time he telegraphed about four daily. The strength of the force is not, however, given and the rates of sickness and mortality cannot consequently be calculated. The bad quality of the water-supply is blamed for much of the sickness.

INFLUENZA ON THE TRAINING-SHIP "ST. VINCENT."

There has been a somewhat extensive outbreak of influenza on the training-ship *St. Vincent* at Portsmouth and a large number of boys are on the sick-list, some of whom have been sent to Haslar Hospital.

Inspector-General of Hospitals Warburton who is greatly respected and is leaving India previously to his retirement from the Indian Medical Service was recently entertained at a farewell banquet at the United Service Club, Lucknow, by the officers of the medical service of the united provinces and presented with an album containing photographs of the donors.

The following officers of the Royal Army Medical Corps have proceeded to Egypt from India for duty with the Egyptian army: Captain H. A. Bray, Captain J. H. Rivers, Lieutenant W. E. Hudleston, Lieutenant S. L. Cummins, and Lieutenant H. G. F. Stallard.

The long-talked-of swimming bath for the use of the troops at Aldershot will soon, we understand, be taken in hand. The bath will be fitted with every modern convenience and there will also be private baths, hot baths, &c.

Correspondence.

"Audi alteram partem."

INFANTILE MORTALITY AND ITS PREVENTION.

To the Editors of THE LANCET.

SIRS,—The success of the movement recently inaugurated for the prevention of consumption and other forms of tuberculosis makes one think that something might likewise be done to prevent the infantile mortality which you so truly say in your issue of Nov. 20th is "a scandal to the municipal authorities and to the State." The figures which you quote in regard to Manchester are appalling, but unfortunately they are little worse than what may be found in any of our other large towns. In Scotland in 1894 (the year for which I have figures at hand) nearly one-fourth of the total number of deaths occurred in children under one year. In Glasgow (same year) the death-rate for all ages was 2·35 per cent., while for children under one year it was 17·65 per cent. In Dundee and Aberdeen the death-rate for those of one year was even higher, being over 20 per cent. in both cities. It is needless to quote more figures for it is sufficiently evident and sufficiently well known that our country loses as many citizens by its high infantile mortality as it does by harbouring in its midst the various forms of tuberculosis.

Of course it may be urged that a high mortality during the first year of life is unavoidable and that in spite of numerous sanitary reforms the infantile mortality is just about as great to-day as it was 30 years ago. That may be true. But it is also true that the death-rate of children under one year is nearly twice as great in town districts as in rural districts and in some of the poorer-class town districts four times as great as in the better-class districts of the same town. This, at least, is found to be so in comparing the death-rate in different districts of Glasgow. The meaning of these figures, I take it, is that a high death-rate among children is not unavoidable.

What, then, is the cause of this high mortality and how is it to be prevented? It is difficult with any degree of certainty to get at its exact cause, but if you ask the opinion of any dozen medical men whose practices lie in the poor parts of the city the one reply will be "bad feeding." For some years past I have made it my custom to inquire as to the feeding of every child brought to me at the out-door department of the hospital and in most cases the wonder is that the child still lives. Parents of this class seem to give their children, even when a few months old, a share of the food which they themselves are eating, and when the child is weaned the "general run of the house" seems to be the customary diet. Statistics tell the same story. Unsuitable food, we know, is the most common cause of diarrhœa in children, and diarrhœa among poor children is very frequent. This is well illustrated by comparing the deaths due to diarrhœa occurring in different districts of the same city. In Glasgow, *for instance, in most* of the poorer districts the death-rate of children under five years from diarrhœa is from three to four times as great as in the better-class districts.

Let us take it, then, that the chief cause of our infantile mortality is bad feeding, how is the evil to be prevented? The first step would seem to be to instruct parents as to how their children should be fed, for the ignorance even with the better class on this point is often amazing. A committee of experts should be formed to draw up a diet-table for children at various ages. These tables should be printed and disseminated among the people in every way possible. When parents register their children they should receive a diet-table and all dispensaries and medical men and, indeed, all persons visiting among the poor should be freely supplied with them. The circulation of such tables would in time bear fruit and parents would come to appreciate the fact that there is a right and a wrong way of feeding their children.

But to instruct the parents is but a preliminary measure, for many parents cannot afford the food which we tell them their children should have. It is not at all uncommon for a working man to have three children all under four years of age, and to give each of these from threepennyworth to fourpennyworth of milk in the day is quite beyond his means. For this class the only solution seems to be to give free food as we give education. And why not? Is it not more important to the State and to the individual that a child should enter life with a healthy body than that he should be able to read and write? The latter can be amended, not the former. It is doubtless a very large order to feed the children of the poor. So was free education. And is not the evil sufficiently great to demand such treatment? The evil of bad feeding does not end with a high death-rate. If that were so it would not so much matter. But of those who survive we have many growing up puny and deformed, stunted in body and in mind, and a perpetual expense to the community in which they dwell. Indeed, it seems much better to feed children as such, in their own homes, than to feed them as adults, as we do, in our unions, asylums, and prisons. The giving of free food would, of course, be very liable to abuse. That would have to be safeguarded. Parents earning a good wage would not be allowed free food for their children, and if they failed to provide suitable food they would be prosecuted under the present law or some future one more stringent.

I am, Sirs, yours faithfully,
WALTER K. HUNTER.

Glasgow, Feb. 2nd, 1899.

MEDICAL ACCOMMODATION IN "TRAMP" STEAMERS.

To the Editors of THE LANCET.

SIRS,—The wish expressed in my letter to THE LANCET of Dec. 17th, 1898, that Dr. Owens would publish an account of his single-handed operation on board the s.s. *Nineveh* which induced the owners to make the operator a suitable presentation has been speedily gratified by the communication in your journal of Jan. 7th—"Herniotomy plus Laparotomy successfully performed under Unusual and Difficult Circumstances." Dr. Owens's inventive resource and bold surgery undoubtedly saved the man's life. To the hope expressed in the opening paragraph, everyone who reads the narrative will say "Amen," while the surgical deductions that conclude the paper are practical and obvious. The true lesson, however, the kernel of the matter, is to be gleaned in the body of the paper and causes one to ask why steamers are permitted to go on these long voyages with such an imperfect outfit and such meagre and inadequate accommodation for the surgeon? The dimensions of the cabin (the operating-room and presumably the sleeping-quarters of the medical officer of the ship) are mentioned as six feet by five feet six inches. The great liner, travelling at railway speed across the Atlantic, is under Board of Trade supervision; every appliance is furnished by the company and the trusted surgeon has *carte blanche*. The trip is brief—under seven days. On the other hand, there is a class of steamers dawdling to the uttermost parts of the earth, facetiously called "tramps" by the regular liners; I do not certify this appellation to the *Nineveh*, which, I believe, is a regular voyager, but there are steamers that are subject to no surveillance save that of the owners or agents. They advertise that the ship carries a surgeon and the contract is kept in the eye of the law so far; but anyone who reads between the lines of Dr. Owens's history of the trip will discern that the whole bill is not filled, and that the necessary *addenda* to the equipment of that officer, such as fresh and pure drugs, proper instruments, with the necessary space, are sadly lacking. So long as the ship gets clearance legally, makes the voyage, and pays dividends—and these plebeian voyagers pay better than the aristocrats of the sea—precious little interest is taken in that necessary evil, the "surgeon and his fixings." I was curious to learn the cause of such unusual appreciation on the part of the owners; certainly no presentation was ever more worthily gained, but I am ungracious enough to think there is also an air of *placebo* about it. Cases are not altogether surgical at sea. Take the other side of the question. A man and his wife and children going to Australia. The man says to his wife: "You need'nt bother about medicines as there is a doctor on board and he will have all that is necessary." Alas for the medical officer and the family. The surgeon, perhaps going on board an hour before the ship is sailing, absolutely uninformed as to the instruments and drugs on which the lives of those committed to his care depend, while the passenger—well, the necessaries are sometimes not to be found and the losses that have occurred in the past through this incompleteness will not be known here. However, it is superfluous to add words further on this subject. The question still presses: Why are these steamers not subject to the searching eye of the authorities? If there be any justification for the suggestions in this letter it is to be found in a perusal of Dr. Owens's experience during his trip to Australia.

I am, Sirs, yours faithfully,

Bournemouth, Jan 31st 1899. R. A. CALDWELL.

POINTS IN THE WORKING OF THE WORKMEN'S COMPENSATION ACT, 1897.

To the Editors of THE LANCET.

SIRS,—The experience which I have had in the examination of accident claims during many years and of the working of the Workmen's Compensation Act, 1897, since last July enables me to endorse in every way the points in your annotation in THE LANCET of Feb. 4th. Firms and insurance offices which carry employers' indemnity risks are being shot at from every side, not only when disease complicates a *bonâ-fide* accident, but in many cases fraudulently when an alleged accident is invented to cover the result of pre existing disease. This is notably so, as you mention in connexion with phthisis or Bright's disease, but I have often had cases of old-standing hernia, disease of the eye, and rheumatic affections which were all stated to be the result of recent accident. Of course, every effort is made to hoodwink the medical examiner and to hide from him the true history of the case.

I wish to call your attention to a matter I have not yet seen publicly noticed and to ask for your opinion in relation to it. In regard to the medical referees appointed by the Secretary of State it is set forth in the second schedule, section 13, "that a committee, arbitrator, or judge may appoint any such practitioner to report," &c., but this has become in many districts a dead letter. County-court judges, even when there is a direct conflict of medical evidence, give decisions without calling for the report of the medical referee provided by the Act. A county-court judge or other learned lay arbitrator, however learned in the law, is not able to appreciate medical evidence from the point of view of an experienced medical man. If the "may" was altered to "shall" judgments would be more in accordance with justice than they often are at present.

In conclusion, in reference to the fees of house surgeons I think that frequently a medical examination by the medical officer of an employer is incomplete and unsatisfactory unless he has before him the medical history of the case; sometimes, however, it is unnecessary, but before seeing the case it is impossible to decide whether it is necessary or not. It would be convenient if the house surgeon could always be consulted with, but the present fees demanded—£1 1*s*., £2 2*s*., and even £3 3*s*.—are absolutely prohibitory in claims where very small compensation is in question.

I believe it would be to the advantage of house surgeons if a small fee was the rule and I feel sure that most insurance offices and firms would willingly pay a fully satisfactory further fee when an exceptional amount of time was taken up or a written report was required. An authoritative word from you on the subject would be of great value.

I am, Sirs, yours faithfully,

ALBERT BENTHALL,
Head Office Medical Officer, Ocean Accident and Guarantee Corporation.

Cockspur street, Pall Mall, S.W., Feb. 4th, 1899.

⁎ It is clear that the fees asked by house surgeons should bear some relation to the demands made upon their time and to the pecuniary importance of the case. We shall refer to the matter later.—ED. L.

"THE DISTRIBUTION AND ORIGIN OF TUBERCULOSIS IN CHILDREN."

To the Editors of THE LANCET.

SIRS,—Dr. Leonard Guthrie in his interesting and valuable paper in THE LANCET of Feb. 4th arrives at the conclusion that children most commonly become infected through the respiratory, not through the alimentary, tract. Most other pathologists who have paid attention to the question have expressed their opinion upon the point still more strongly. Thus, Dr. Comby[1] in 28 cases of tuberculosis occurring in children under the age of two years considered that infection took place through the respiratory tract in every instance; in all caseation of the mediastinal glands was present. Dr. Emmett Holt[2] in 119 necropsies found the bronchial glands affected in 108 and did not consider that infection through the intestinal tract occurred in more than 1 or 2 per cent. of the cases. Dr. Holt quotes Northrup as having in 125 necropsies on cases of tuberculosis in children found what appeared to be definite infection through the intestinal tract in only one instance, whereas there were 88 in which it was obviously through the bronchial glands. My own experience of post-mortem examinations in young children is so small as to be scarcely worth mentioning, but in 10 cases of tuberculosis in children aged two years and under there were caseous bronchial and mediastinal glands in nine; in four of these there were caseous points in the mesenteric glands also, but in one case only caseation was present in the mesenteric glands, while the bronchial glands were unaffected. Dr. Guthrie seems to doubt that the intestinal tract frequently becomes infected secondarily to the respiratory. He appears to think that extensive lesions of the lung must first be present. Caseation of the bronchial glands, however, probably not infrequently follows a bronchitis set up by tubercle bacilli. I have seen tubercle bacilli swarm in the sputum of an adult suffering from what appeared to be an ordinary attack of acute bronchitis. Dr. Guthrie also agrees with Dr. Woodhead that caseation of the bronchial glands need not necessarily indicate infection through the respiratory tract. Cases may occur occasionally in which the infecting bacilli have arrived from a distance, but instead of there being a danger of attaching too much importance to the bronchial glands as indicating the channel of infection one would think that in many instances the primary focus of the disease when situated in them may be overlooked. Should the mediastinal glands not also be affected the bronchial glands when not specially looked for may easily escape notice. While, however, Dr. Guthrie does not express such a decided opinion as some as to the infrequency of infection by the digestive tract he is not prepared to admit that abdominal tuberculosis when present necessarily indicates that the disease has been derived from cows' milk. He suggests that milk or food may become contaminated by tubercle bacilli in the air, and to this suggestion another may be added, that the kissing of a baby by a phthisical woman may not uncommonly be a source of infection by leaving mucus containing bacilli on the child's lips. So far as I am aware it remains to be proved that the bacilli of bovine tuberculosis are virulent towards man. Dr. Emmett Holt relates an experience that seems to point in the opposite direction; 45 per cent. of the cows of a dairy, which had for several years supplied many families in a large American city were found to be tuberculous. They were killed, and an investigation was started. Of the many hundreds of children who had drunk the milk, only one was found to be tuberculous. I am, Sirs, yours faithfully,

---

THEODORE FISHER.

Clifton, Bristol, Feb. 4th, 1899.

"TREATMENT OF VARIOUS INFLAMMATORY PROCESSES BY THE EXTERNAL APPLICATION OF ALCOHOL."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 28th Dr. Zangger refers to the good results obtained in cases of whitlow, lymphangitis, incipient abscess, &c., by the application of alcohol. For the last seven years I have had equally good results from the use of carbolic acid (one in 60) applied on lint and covered with protective. I have particularly noticed the relief in my own case when having infected my finger while performing a post-mortem examination I was kept awake by the pain and throbbing. Carbolic acid (one in 60) applied as above and changed three times a day quickly relieved the pain, rendering the finger white and partially insensitive. Sometimes a bead of pus has formed beneath the skin; sometimes not. The carbolic acid relieves tension and limits absorption by contracting the blood and lymph vessels and at the same time acts as a local anæsthetic. I have no very high opinion of carbolic acid (one in 60) as a germicide when applied directly to an infected area, and it appears far-fetched to think that it kills bacteria through an unbroken skin surface. One word of warning. I have come across several cases (and there are a fair number on record) in which the continued application of carbolic acid to fingers has resulted in complete arrest of the circulation followed by gangrene. Patients are apt, unless warned to the contrary, to continue the application for many days and owing to the freedom from pain do not notice that anything is amiss, and the first thing noticed may be that the fingers on being incised fail to bleed, being in a state of dry gangrene. Anæmic young women are especially liable to this mishap.

I am, Sirs, yours faithfully,

C. HAMILTON WHITEFORD.

Plymouth, Feb. 6th, 1899.

"AN ALCOHOL BATH FOR BURNS."

To the Editors of THE LANCET.

SIRS,—Mr. Wilfred Watkins-Pitchford's letter in THE LANCET of Feb. 4th on the suggested treatment of burns by an alcohol bath reminds me of an experiment on somewhat similar lines, though without using alcohol, I made some years ago while I was house surgeon at the Oldham Infirmary. Recognising the very unsatisfactory treatment of bad burns by ordinary methods, and having to deal with a very severe and hopeless case of burning in a little child, the greater part of her body surface having been burnt, and on account of the great pain caused by changing the extensive dressings, and, on the other hand, the great fœtor produced by leaving them unchanged, I decided to try treatment by a bath. After thinking the matter over I improvised a sort of bath by raising the edges of the large macintosh upon which the child was lying and secured them all round to the top of the railings of the child's cot, and then filled the hollow so produced with the child in the middle with carron oil (equal parts of olive oil and lime water). I chose carron oil partly on economic grounds and also because I considered it would probably be as good a dressing as any other for the purpose I had in view. The oil was kept sufficiently warm by the nurse adding a little warmed oil constantly and was changed whenever necessary by lowering the mackintosh at the foot-end of the bed and running it off. The result for the few days that the child lived was perfectly satisfactory as far as the child's comfort was concerned and the fœtor was entirely destroyed. One danger had to be guarded against and that was the danger of the child slipping down into the oil and getting drowned. This, however, was prevented by securing the head and shoulders above the level of the oil by bandages fastened to the metal work of the cot. Although I have not since had an opportunity of again trying similar treatment I feel convinced that some such treatment would be a great improvement on the usual very painful and unsatisfactory methods. I am, Sirs, yours faithfully,

JOHN J. WEAVER.

Southport, Feb. 4th, 1899.

HUNTER *v.* CLARE: THE REAL QUESTION.

To the Editors of THE LANCET.

SIRS,—Your calm and sensible leading article on this case in THE LANCET of Jan. 28th deserves the thanks of all right-minded men in the profession. There is a deeper issue at stake than the mere right of a particular individual to style himself in a particular way. The real question is this: Is it, or is it not, desirable that a large number of the weaker and less industrious students should pass under the ægis of a non-professional body? for such the Society of Apothecaries really is, having no discipline over its Licentiates, merely the power to remove them from its roll for felony or when previously struck off the Medical Register; that they should be encouraged to take a diploma (which is not recognised as even partially equivalent by any other qualifying body and which therefore debars them to a great extent from ever rising to the higher ranks of the profession) by the inducement held out to them that it confers upon them the power to pick and choose any titles they prefer from among those accepted commonly (?), which injunction they nearly all carry out by annexing the lot (I speak from personal observation), covering their houses with multitudinous plates inscribed Doctor, Physician, Surgeon, and Accoucheur, and emblazoning their lamps with similar inscriptions, while the lack of restraint on their actions by the qualifying body permits *some* of them to indulge in such doubtful practices as circularising, handing of cards over chemists' counters, touting from door to door by club agents and insurance touts? Any one of the *old* L.S.A.'s can by passing an examination in *surgery* acquire the *new* Licence. Does that therefore make him a physician? We who practised on the M.R.C.S. and L.S.A. before 1886 used not to think so or so many of us would not have taken a degree or an L.R.C.P. in addition. Moreover, the L.R.C.P. is forbidden by the terms of his Licence to dispense medicine except for those who are his own patients, and therefore to keep an open surgery such as is so common in London and which is, I take it, the special prerogative of the L.S.A. The whole business has been the outcome of the very proper refusal of the College of Surgeons to combine under the provisions of the 1886 Act with a non-professional body in granting a joint licence, and no one interested in the true welfare and dignity of the profession can blame them for doing *so* or the General Medical Council for endorsing their own approval of that action at the time by now preventing the continuance of a grave scandal—a game of bluff on the part of the Apothecaries, the victims being the public quite as much *as the* other members of the profession. It is a strange thing that in the London *local* directories I have examined the letters L.S.A. never occur, while other diplomas and degrees are detailed, the words "physician and surgeon" being alone given. Is this honest or is it a rather dishonest attempt to conceal a qualification in order to get practice?

I am, Sirs, yours faithfully,
WM. J. T. BARKER,
M.R C.S. Eng., L S A., L.R C.P. Lond, D P.H. Camb.,
Formerly Physicians' Assistant, Bristol
General Hospital.

Fulham, S W., Feb 6th, 1899

"REGINA v. REICHARDT."

To the Editors of THE LANCET.

SIRS,—With regard to the letter of your correspondent Dr. Goodhart, as yet unchallenged and which appeared in your issue of Jan. 28th, seconding the appeal advanced by Dr. Savage on behalf of Dr Reichardt, it would be interesting to know how Dr. Goodhart differentiates between what he pleases to call "temporary unsoundness of mind" and what is known in popular phraseology as "temporary insanity," as it might appear in a definitional sense a point which more concerns experts in etymology than experts in lunacy.

It is certain, however, that if patients are received in uncertified houses suffering from "temporary unsoundness of mind" the recipient of such patients treads perilously on the heels of the law, and it cannot therefore be a matter of surprise if one of such cases unfortunately culminates in suicide that the Commissioners should feel it their duty to test the position of the medical practitioner involved in a court of law. For this reason it might suggest itself that Dr. Reichardt having assumed a responsibility which he was not called upon to assume it would follow that the case is one that can scarcely commend itself for public commiseration, although I apprehend no member of the medical profession grudges *Dr. Reichardt his verdict.*

I am, Sirs, yours faithfully,
CLEMENT H. SERS.

Queen's road, Peckham, S E., Feb 3rd, 1899.

THE EXPERIENCES OF A PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—In view of the fact that many public vaccinators (like myself) have their fees yet to be fixed by the Local Government Board my first month's experience in a London district may be of interest One solitary parent made a requisition! My vaccination officer sent lists of 107 children who had attained the age of four months. Of these I vaccinated 23 only, eight were out, five gone away, 10 promised to "let me know," three declined the operation absolutely, 11 were already done, seven in two places, four in one place! I came across one family of four unvaccinated, the mother consenting to have the whole done; another family of seven whose father preferred to "brave the penalties of the law," 18 promised that their own doctors should do it, and the rest were postponed. Looking at the time occupied and the character of the business I do not feel elated at my prospects!

I am, Sirs, yours faithfully,
S. E. DISTRICT.

Feb 8th.

THE FEES DUE TO THE NON-RESIDENT MEDICAL OFFICER OF A WORKHOUSE.

To the Editors of THE LANCET.

SIRS,—I should be glad of information on the following points:—1. Is the medical officer (non resident) of a workhouse entitled to a fee at the time of the examination of a patient by a magistrate for the purpose of making out a "detention order"? 2 In the case of the detention order being on account of insanity would the medical officer be entitled to a fee for the examination for the purpose of "certifying" the patient for removal to an asylum as well as when the preliminary detention order is made? 3. In the above what fees are usual? 4. Is a workhouse where the inmates are vaccinated by its medical officer who is not otherwise a "public vaccinator" a "vaccination district" within the meaning of the Act (Clause 4)? Does the clause of the General Orders of the Local Government Board relating to the medical officer (No. 208, 5) prevent the officer from being entitled to a minimum fee of 2*s*. 6*d*.? 5. Is the fee usually now 2*s*. 6*d*. or greater than the minimum.

I am, Sirs, yours faithfully,
WORKHOUSE.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Commission.—The Progress of the Plague.—Professor Lustig in Bombay.—Criticisms on Inoculation.

A GREAT deal of the evidence given before the Plague Commission is most uninteresting and consists of repeated accounts of the measures taken at different places for the control of the epidemic. I extract the most important particulars only. At the sitting in Agra Colonel Thomson, I.M S., the Sanitary Commissioner, advocated that when plague broke out in a village the village should be evacuated, the people accommodated in huts, and the hamlet burnt down, and that in a small town a large block all round the focus of the disease should be evacuated, every house being thoroughly disinfected, and every hut burnt. The people should be kept in camps for at least one month. Captain White, I M.S, said that he thought that accidental inoculation by abrasion of the surfaces of the skin or the mucous membrane was the exception rather than the rule in plague and he doubted whether abrasions were sufficient to account for the large number of femoral, inguinal, and axillary buboes amounting to about 75 per cent. of the total cases. On account of the position of the buboes one ought to look for some peripheral point of inoculation which was difficult to find. He did not think that abrasions of the skin on the hands and feet were common among the natives Captain Elphick, I.M.S., gave a pathological account of the Jarvalapur plague cases. Of 35 cases presenting no external bubo all but one died Of these 19 were of the pneumonic form and 15 were considered to be of the so-called septicæmic type. One had internal buboes. One only of the septicæmic type recovered In all the cases examined post mortem there was œdema of the front chest extending to the upper arms, the sides of the chest, and the abdomen. In every case there was some enlargement of the mesenteric glands Colonel Adams, I M S, thought that the outbreak in the Sirdhi State demonstrated that germs of the disease were carried to great distances in clothes. On Jan. 19th the Plague Commission took evidence at Lahore. Captain James, I.M S., thought that in the majority of cases human agency was responsible for the outbreaks, whilst in some instances it was due to rats. These sometimes spread the disease by moving from village to village. He thought that rats coming in contact with clothes infected them. He had observed that infants in arms seemed to be immune. Out of 13 infants nursed by their plague-stricken mothers only one fell sick. The disease was milder in children than in adults He recognised a form of the disease so mild as to permit the patients to move about. He considered the cordon a failure because the police force was not, only insufficient but corrupt.

The Bombay Presidency returns for the week ending Jan. 13th show 2593 cases and 2045 deaths. Last week the figures were 2537 cases and 2048 deaths. For some weeks past there has been a steady decline, but this increase in the number of reported cases is due to the development of the recrudescence in Bombay city where the fatal cases have increased by more than 100. In Kolapur plague also has increased. There are now throughout the Presidency 360 villages affected With regard to the value of train inspections it is to be noted that at all the railway stations where inspections are carried out only 35 cases were detected. The Madras Presidency returns show that 78 villages are infected, against 63 in the previous week. In Bangalore city and cantonment there is a great improvement From August 12th, 1898, when plague first appeared in this Presidency, up to Jan. 13th there have been recorded 11,607 cases and 9750 deaths. Madras city continues free. In Bombay city the increased mortality is very marked. During the past week there have been 307 deaths from plague recorded, as compared with 219 for the previous week, but the total mortality has risen from 1111 to 1239—a rate per 1000 of 75 87. This is more than double the weekly mortality

(604) of the middle of November which was probably the normal death-rate for the present increased population of the city. Unfortunately there is reason to believe that by far the greater part of this excess mortality is due to plague.

Professor Lustig is going shortly to Bombay to superintend the manufacture of, and to experiment with, his curative serum. During the last outburst of plague in this city this serum was extensively tried, but the results were not particularly satisfactory and certainly not conclusive. There was a great difficulty in bringing it undamaged from Italy, so the municipality of Bombay voted a sum of money for its manufacture in Bombay. This, therefore, has been going on during the past few months and the fresh serum is now ready for use. The number of plague cases admitted to hospitals is now under the existing regulations very small, but in testing for the value of this fresh supply it is to be hoped that the cases will be taken on admission *seriatim* and not picked out as for the former experiments. Unless this is done the statistics will be almost valueless.

The advantages of inoculation are not confined to the prevention of plague, but the inoculated who get plague suffer less risks. At a plague hospital in the Mofussil there have been admitted 51 cases of plague amongst persons who had been inoculated; of these 21 had been once inoculated and 30 twice inoculated. The deaths up to date had been 19, composed of nine among the once inoculated and 10 amongst the twice inoculated. This gives a mortality of only 37 amongst the inoculated, or more particularly of 43 per cent. among the once inoculated and of 33 per cent. among the twice inoculated. These figures would be increased somewhat by any deaths among those remaining now under treatment, but as the death-rate from plague among the uninoculated and general population averages from 70 to 80 per cent. these returns show the decidedly protective effect of inoculation. Plague among inoculated persons is characterised also by much less mental disturbance. There are less delirium and less obfuscation of the mental faculties. Considerable criticism has been made of M. Haffkine's prophylactic fluid by various witnesses before the Plague Commission. Colonel Lawrie, I.M.S., says it is a putrescent organic liquid. Dr. Nield Cook of Calcutta says that he discovered sarcinæ in it and what appeared to be the bacillus mesentericus fuscus. Captain Johnson says that some samples contain cocci, others a mixture of cocci and bacilli, and that many of the organisms are distinctly pathogenic, some more virulently so than others. He goes so far as to say that the fluid as received now from Bombay is undoubtedly a putrescent organic liquid.

The migration of rats is probably a not unimportant factor in the dissemination of plague. Rats are known to migrate from one district to another when they find apparently that their numbers are being killed off by plague. They have also been observed to forsake certain houses or blocks of houses where they have apparently scented danger. It is an old observation that they have been known to run away from an impending epidemic. Rats also at normal times appear at places in large numbers unexpectedly or at places not usually frequented by them. It is stated that recently large numbers were seen crossing the causeway from the island of Bombay to the mainland.

Jan. 21st.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Infirmary.

NEGOTIATIONS with the corporation for the sale of the infirmary site are going on, but there is no knowing at present what the result will be. The feeling, however, seems to be tending, much more than used to be the case, towards the sale of the whole site and the removal of the infirmary to a site in Oxford-road which has many advantages in addition to its proximity to Owens College. Such a consummation is to be wished for in the interest both of the infirmary and the city. In the meantime, as the report says, during the past year "the functions of the infirmary have been discharged with their wonted regularity"; 4533 in-patients and 33,443 out- and home-patients have been treated during the year. The income and that of the Barnes Convalescent Home at Cheadle was £25,752, a decrease of £362 on the previous year, due chiefly to diminished annual subscriptions. The expenditure at the infirmary was increased by the building of a new clinical laboratory which cost rather more than £400. At present the infirmary contains 293 beds and the Convalescent Hospital at Cheadle 136. If the infirmary is removed the difficulty of increasing the number of its beds will also be removed.

The Lunatic Hospital.

The Lunatic Hospital at Cheadle is part of the institution comprised under the name of the Manchester Royal Infirmary and is, of course, quite distinct from the Convalescent Hospital also at Cheadle. There is always great pressure on its space and the committee have recently sanctioned the enlargement of the St. Ann's Hospital in the near neighbourhood of the asylum which is devoted to epileptic cases. The committee share in the opinion often expressed by the superintendent, Mr. Mould, "that the main building of the asylum should as soon as practicable be chiefly reserved hereafter for cases requiring active treatment, those of a chronic character being suitably located elsewhere and in a separate building." In order to carry out this object additional land contiguous to the asylum property has recently been acquired. There are 350 beds in the asylum and its branches, and the cry is ever for more room.

Gas Accidents.

Two occurrences in the neighbourhood of Manchester illustrate the dangers connected with lighting and heating with gas. The first shows that gas companies should watch more closely for leakage from the mains to protect themselves from loss and the public from death. On Feb. 5th, at Stalybridge a man was found in his bedroom suffocated by gas which had escaped from a broken main. His wife and two grown-up children were found unconscious. In another house the husband was awakened by his dog scratching at the bedroom door and, as the report says, "making other noises as if in distress." The man, his wife, and baby got downstairs and found the house full of gas. The air about three houses in the street—Nos. 9, 11, and 13—was, as it was said, "pregnant with gas." Nothing had been seen of those living in No. 11, and as the police sergeant was going to knock at the door an explosion took place which blew out the windows and door and caused great destruction inside. A young man, a son, was lying on his face, apparently dead; a daughter was in bed unconscious; and the father was found lying dead on the floor. His wife was in bed and unconscious. It was thought that but for the warning given by the dog there would have been several other deaths. This brings to mind a curious instance of the effect of leakage from a gas main. A gentleman's grapes did not thrive and after a time the gardener who had done his best gave up his place. They fared no better under his successor and no one could divine the cause. But one day the owner lighted a match and threw it down when the floor of the vinery was lighted with a lambent flickering flame. The other tragedy in which three people met their death took place on the same day near Oldham. In this case they were suffocated by the fumes from a gas stove. The fireplace had been bricked up, the door was shut, and there was no outlet for the fumes. There seems room here, at all events for the good of the coming generation, for the addition of a little useful knowledge to what is already taught at board and other schools.

Manchester Port Sanitary Authority

At the monthly meeting of the Manchester Port Sanitary Authority held yesterday, Dr. Crocker, the medical officer of health, reported that he had inspected 119 vessels during the last month, of which 99 were British and 20 foreign vessels. Defective or insanitary conditions were found on 19 British and on two Norwegian ships. This does not redound to the credit of the British ships or their owners. It is satisfactory to learn that no infectious cases were reported. It was moved and carried that in accordance with the recommendations of a sub-committee, "in addition to the authorities of Manchester, Salford, and Stretford which have hitherto formed the Port Sanitary Authority, the Runcorn urban, the Runcorn rural, and the Wirral rural sanitary authorities, shall in future form such authority, and shall bear the expenses of the authority in proportion to the representation on the board." It was also resolved to recommend to the Local Government Board that in addition to this in the event of any ships coming up the canal with infectious cases on board the authority to whose district the vessel was first destined shall pay for the maintenance and medical attendance of such patients.

Feb. 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Cameron Prize of the University of Edinburgh.

THE Cameron prize of the University of Edinburgh which is conferred on persons who have made valuable additions to the subject of practical therapeutics has, on the recommendation of the Faculty of Medicine, been awarded by the Senatus Academicus to Dr. Monckton Copeman of the Local Government Board, London, in recognition of his researches on the employment of glycerine for destroying pathogenic organisms in vaccine lymph.

Edinburgh Public Health Committee.

At a meeting of the Public Health Committee of the Edinburgh Town Council held on Jan. 31st it was stated that the cost of reporting cases of infectious disease for the last half year amounted to £542, representing 4339 cases.

Society of Chemical Industry.

At a meeting of the Scottish section of the Society of Chemical Industry held in Edinburgh on Jan. 31st, after the reading of papers by Mr. E. O. C. Standford on a new apparatus for the purpose of automatic infusion and by Mr. G. D. Macdougal (Dundee) on a new apparatus for the rapid analysis of milk, a discussion took place on milk-supply, in which part was taken by Dr. Tatlock, Mr. Falconer King, Dr. Marshall, Mr. L. Watson, Dr. Foulis, and Dr. Aitken. The opinions were expressed that there ought to be a standard for milk fixed by Parliament and that legislation was required dealing with the question of tuberculosis in relation to milk, to the operation of milking, and to the subsequent treatment of milk. Dr. Foulis stated that in his practice 80 per cent. of the cases of scarlet fever had been caused by infection through milk.

Students' Conference in Edinburgh.

The annual conference between members of the Students' Representative Councils of the Universities of Edinburgh, St. Andrews, Glasgow, and Aberdeen was opened on Feb. 3rd by Principal Sir William Muir in the hall of the Edinburgh University Union. Various reports were presented and motions brought forward, among these being a report by the Edinburgh International Academic Committee stating that arrangements were being made for the appointment at foreign university seats of "consuls" who would take an interest in Scottish students going abroad to pursue their studies. The conference was resumed on Feb. 4th, and among other business the question of the employment of the fifth year in medicine was discussed. It appeared that there was a tendency to employ it in attendance at lectures rather than as a year for practical work. It was also moved and carried that the councils be recommended to urge on the authorities the necessity of providing for two final examinations in medicine in the year, so that it might not be necessary for students who had failed to wait for a whole year before again entering for examination.

Glasgow Hospitals.

At the annual meeting of the qualified contributors to the Glasgow Royal Infirmary held on Jan. 30th the Lord Provost, Sir David Richmond, in moving the adoption of the report gave some information of the present position of the reconstruction scheme. He stated that though little apparent progress had been made a great deal of work had been done. The managers were determined that the new hospital should be constructed and equipped in harmony with the best ideas of the day. To realise this end much trouble had been taken and at last the sketch-plan of the internal arrangements had been approved both by the staff and the committee. It was hoped that in the course of a few weeks all the plans would be finally adjusted. The total sum subscribed was £82,000 and the committee trusted that the balance necessary to realise £100,000 would yet be collected. Later in the meeting, as previously intimated, Colonel Denny, M.P., moved the election of two ladies as directors of the infirmary in opposition to the official nominees. Mr. Faithfull Begg, M.P., supported this proposition and a somewhat lively debate ensued. On a vote the ladies were defeated by 85 votes to 26.—The report of the Royal Hospital for Sick Children was submitted to the annual meeting of the subscribers on Jan. 28th. In moving its adoption Dr. Hector C. Cameron alluded to the considerable deficit in the financial account as a matter demanding public attention. He urged that all possible economy was practised in the management of the hospital, but it must be remembered that to give the patients the full benefit of medical science demanded the same expenditure as was necessary to secure the same ends for private patients. Death would not be held at arm's length on cheap terms. Dr. Cameron also spoke in opposition to the proposal to put the hospitals on the public rates.—The Glasgow Central Dispensary has lost the services of Dr. J. B. Russell as chairman in consequence of his removal to Edinburgh. At the unanimous wish of the board Dr. Russell has consented to remain on the directorate.

Medico-Legal Appointment.

Dr. J. Glaister, F.R.S.Edin., D.P.H. Camb., Professor of Forensic Medicine in the Glasgow University, has been appointed one of the medico-legal examiners in Crown cases for the city of Glasgow in place of the late Professor Coats.

Faculty of Physicians and Surgeons, Glasgow.

Mr. J. Hogarth Pringle, M.B. Edin., F.R.C.S. Eng., has been admitted a Fellow of the Faculty.

Queen Margaret College, Glasgow.

A very sad incident has darkened the course of the session. One of the most brilliant of the medical students, Miss Grace L. Young, died last week after only a few days' illness. She had passed through her curriculum with great distinction and in the ordinary course of events would have graduated in July next. Her personal influence not less than her abilities was appreciated in all the college faculties and her early death is the cause of general grief.

Glasgow Medico-Chirurgical Society.

This society met for the eighth time on Feb. 3rd when Dr. Hinshelwood showed for Dr. McCall Anderson a typical case of Psoriasis Rupioides occurring in a girl of nine years of age. Dr. John Love showed: 1. A case of Locomotor Ataxia associated with Diabetes Mellitus. The ataxia had developed with great rapidity. There had been some improvement of late under Frankel's method of re-education of the muscle sense. 2. A case of Locomotor Ataxia with Charcot's Joint Affection very typically developed in the left knee and commencing in the right. 3. A case of Pseudo-hypertrophic Paralysis of four years' duration beginning at the age of 14 years. The case was an isolated one, there being no nervous history in any other member of the family.

Proposed Home for Phthisical Patients near Aberdeen.

The annual report of the Cottage Home for Convalescents at Newhills states that during the season of 1898 165 persons were admitted, most of whom left in greatly improved health. It is proposed to add to the cottage a wing specially constructed for the use of phthisical patients so as to admit of a limited number of cases in the early stage of the disease being treated, as far as climatic conditions will allow, on the open-air system. Such cases, as a rule, have been greatly benefited by residence at the cottage. The financial position of the institution is at present satisfactory and encouraging. Last year there was a surplus of £84 and there is also a reserve in the bank of £75.

Aberdeen Royal Infirmary and Asylum Corporation.

The annual report by the directors of the above institution shows that during 1898 there were admitted to the infirmary wards 2605 patients, while there were also 5692 out-patients, as compared with 2177 and 5557 respectively in the previous year. The deaths in medical cases numbered one in 12·1 and in surgical cases one in 25·9, as compared with one in 9·8 and one in 21·3 respectively in 1897. The curative work and nursing have been effective and satisfactory. The new ward for diseases of women is stated to be an important department and the receiving and operating rooms for eye diseases have been improved and enlarged. There were on an average 40 more patients a day than in 1897, and while the total income increased to £8963 7*s.* 11*d.* the total expenditure rose to £10,215 5*s.* 10*d.* The cost per bed which in 1897 was £51 14*s.* 5*d.* was by economy reduced in 1898 to

£47 16*s.*, being a saving of £3 18*s.* 5*d.* on each of the 196 beds occupied. At the Convalescent Hospital, Cults, near the city, 300 patients were received, as against 175 in the previous year, and the cost per patient was £1 15*s.* 5*d.* A house-to-house collection of contributions will be started in June by the Hospital Saturday Committee to aid the upkeep of the infirmary on its enlarged scale. As regards the Royal Lunatic Asylum, the number of patients on the roll, which at the beginning of 1898 was 771, rose to 840 at the close of the year, an increase of 69 compared with an increase of 35 during 1897. The interim arrangements to be made in consequence of the proposed erection of a new asylum for pauper lunatics from the city are mentioned and it is not expected that the interests of the Royal Asylum will be prejudicially affected. It is estimated that to give effect to the views of the Lunacy Commissioners the reconstruction of the main asylum will cost £40,000. The cost will be met out of the surplus income. Daviot continues a useful branch and 76 acres of agricultural land were added to the grounds in Aberdeen. The ability of the curative work is certified by the Lunacy Commissioners. The total income for 1898 was £29,482 5*s.* 9*d.* and the total expenditure was £25,376 1*s.* 2*d.* Of the surplus of £4106 4*s.* 7*d.* £2000 are allocated to the reserve and £2000 to the cost of extensions.

Feb. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The City of Dublin Hospital.

DR. A. C. DUFFEY who has filled the office of [illegible] surgeon at the City of Dublin Hospital for the past [illegible] years was presented on Feb. 4th with a testimonial by [illegible] the medical and surgical staff, the resident students and ex-students, and the nursing staff. The members of the senior staff of the hospital were all present on the occasion and, quite apart from the value of the articles in which the presentation took its shape was the fact that such an honour to a young member of the medical profession is in Dublin almost unique, which proves that Dr. A. C. Duffey has performed his duties most efficiently during his long term of office in the hospital, while rendering himself at the same time quite unusually popular with the various members of its staff.

The Professorship of Pathology at Cambridge.

Dr. J. Lorrain Smith is a candidate for the chair of Pathology at Cambridge University, vacant though Professor Kanthack's death. After being John Lucas Walker student and demonstrator of pathology in Cambridge Dr. Lorrain Smith was appointed in 1894 lecturer on pathology in Queen's College, Belfast, and in addition to that post he was selected as pathologist to the Royal Hospital, the Hospital for Sick Children, and as bacteriologist to the Corporation of Belfast. The medical faculty of Queen's College, Belfast, and the staff of the Royal Hospital in that city have forwarded to the authorities at Cambridge a very strong letter on Dr. Lorrain Smith's behalf. Although on academic and personal grounds they would very much grudge his loss to Belfast they cannot but wish him every success in his candidature for the chair of Pathology at Cambridge.

Extraordinary Rainfall in January in Belfast.

In January there were 23 days on which rain fell in Belfast and the total amount for the month was 5·38 inches which is unusually high. In the same month in 1898 there were 13 days with rain and the total rainfall was only 1·67 inches.

Health of Belfast.

The report presented at the City Council meeting on Feb. 1st shows that the health of the city was in a satisfactory condition, the annual death-rate being 22·8 from all causes, while in the corresponding part of 1898 it was 24·1. The deaths from all causes in the past month, as well as those from chest diseases, are fewer than in the preceding month, while the death-rate from zymotic disease has also decreased. Typhoid fever is steadily decreasing but scarlet fever of a mild type is prevalent in many districts of Belfast.

Irish University Education.

The public interest in the university question is increasing. It is the great topic of conversation and the papers are full of speeches and letters on the subject, and almost everyone has his own ideas as to the settlement of the difficulty. One thing is becoming more and more evident, and that is the growing feeling that the present arrangements cannot go on; and the recent action of the Senate of the Royal University is an object-lesson to the man in the street. It would appear that this body met on Feb. 2nd, and although its proceedings are supposed to be private they have become through the press public property. Lord Morris presided and The O'Connor Don moved and President Hamilton seconded a resolution declaring that the present university system of Ireland was highly unsatisfactory. To this the previous question was proposed as an amendment by Dr. Allman, F.R.S., and seconded by Professor Leitch, D.Lit. The division showed that 11 Protestants voted for the amendment, while 12 voted against, all Roman Catholics except two. Of the medical members of the Senate three voted for the amendment and one against. His Honour Judge Shaw then proposed a second amendment that, after the statement in The O'Connor Don's motion, to the effect that the present arrangements for university education in Ireland are not satisfactory, there should be added the words "and that we earnestly press upon Her Majesty's Government the necessity of providing teaching colleges in connexion with this university such as will meet the wants and wishes of the people of this country." The O'Connor Don was not prepared to accept this amendment and the upshot was that it was decided unanimously to adjourn the discussion of the mat[illegible] until the next meeting [illegible] nate, which [illegible]. The divulging of [illegible] he subject of private [illegible] ts of the Royal [illegible] in [illegible] unconscious. In [illegible] by his do[illegible] door and, as the report say[illegible] as if in distress." The ma[illegible] sup- [illegible] got downstairs [illegible] the house [illegible] education see that a change in [illegible] evitable. If a Roman Catholic University [illegible] ed, the question to be solved is how to provide [illegible] education for those Protestants who at present go to the Royal University. There are only two courses—one the establishment, as Mr. Balfour suggests, of a Northern University located in Belfast, and the other the plan of developing Trinity College, Dublin, making it the great Protestant University of Ireland, and affiliating with it Queen's College, Belfast, and the Magee College, Derry. This is the view approved of by the Committee of Higher Education of the Irish Presbyterian Church which met on Feb. 6th and came to the unanimous conclusion, in addition to reaffirming a previous opinion in favour of non-sectarian education, "that no solution of the question of university education in Ireland will be satisfactory or final that does not include the complete nationalising of Dublin University." From a purely arts point of view a good deal might be said in favour of this settlement of the University question in Ireland, but those who put it forward forget that there is a great medical school in Belfast—the only one in the North of Ireland—and that the medical faculty is the right arm of Queen's College, for during the last session out of 398 students 223 attended the faculty of medicine. Now, one of the special grievances that Belfast students have against the Royal University is that their school is not properly represented on the examining boards. Take as an example the M.B. Board; here there are 12 examiners and of these only two are taken from Belfast while over 50 per cent. of the candidates come from that school. Another curious anomaly is that two of the examiners are on the staff of the Richmond Hospital, and as a natural result Belfast students are attracted in this way to attend a winter or summer session in that institution in Dublin. The medical profession in the north feel that if their school were affiliated with the medical school in Trinity College, Dublin, all the evils at present existing would be perpetuated, for there would be an effort not to pit Trinity College against Queen's College, but Dublin against Belfast. But there is another important difficulty in the way. Trinity College does not want to be allied with any other college and hence on all these grounds one is compelled to see that the only practical solution of the question is the one which has been so ably and so thoroughly advocated by Mr. Balfour. It alone really holds the field.

Feb. 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Contaminated Spring Water in Paris.

SOME six years ago a movement was set on foot to increase the amount of spring water available for drinking in Paris, as there is never at any time too much of this necessity of life. Accordingly the Aire, a stream hitherto unused, was pressed into the service and its water brought into the seventeenth arrondissement by means of aqueducts and other works the cost of which mounted up to several millions of francs. The water was very pure and of excellent taste. One month ago, however, it suddenly became yellow and developed a most suspicious flavour. Upon making a microscopic and bacteriological examination it was found that a vibrio was present closely allied to the cholera bacillus. The population of the affected arrondissement naturally began to get somewhat alarmed although no epidemic has as yet broken out amongst them. The engineers of the supply have stated that they were aware of the presence of this vibrio but that it was harmless thanks to the presence of other micro-organisms which kept it in check. An inquiry is on foot and M. Brouardel who has been consulted considers that circumstances point to the infection of the springs at their source, so a searching investigation has been carried out from this point of view. This inquiry took place at Verneuil in the district where the springs rise. It is now established that these springs which were thought to be collected at their real source for the supply of drinking-water are really only fed by subterranean sheets of water of which the source is some long distance away. As a matter of fact, they are offshoots from the River Aire and not real springs—i.e., they have to do with percolations from the river water and are more or less purified by passage through the soil. After the late very dry summer the first rainfall was absorbed very quickly by the thirsty soil so that the first supply of water percolating through was somewhat impure. The most serious part of the matter is that the Aire a little above where it apparently loses the portion of its waters which goes to feed the subterranean sheets of water which supply the Paris aqueduct receives a small stream, the Iton, which runs through the town of Verneuil and thereby serves the town as a kind of sewer. Again the public wash-houses are on the bank of the Aire at about the same level and the use of fluorescine has shown that this colouring agent when put into the water of the Aire can be traced in the reputed springs which serve the town of Paris.

A Sanatorium for Tuberculous Soldiers.

The question of providing a sanatorium for soldiers attacked by tuberculosis has just come before the Chamber of Deputies. The matter has come to a head owing to the alarming and progressive increase which tuberculosis shows in the ranks of young soldiers In 1890 there were 5·70 per 1000 soldiers discharged during their term of service on account of being tuberculous, but in 1895 the figures had reached 8·34 per 1000. For a tuberculous man to live in barracks is not only bad for himself but a source of danger to his companions. As a matter of fact when the malady reaches a certain stage of development the military surgeons send him home. Unfortunately, however, when arrived there he very seldom finds the conditions necessary for his cure. There is therefore the risk not only that the patient will get worse, but that he will also infect his family and his village. The term of military service which is obligatory upon all Frenchmen is a potent agent in the dissemination of tuberculosis throughout France just as it unhappily is in the case of syphilis. The proposed military sanatorium will allow of the immediate withdrawal of all tuberculous soldiers from their regiments and will at once put a stop to their spreading infection either in the barracks or in their own homes.

A Fraudulent Druggist.

The Paris Tribunal has just had to deal with the case of a druggist who falsified his pills and potions with an audacity which is happily uncommon. He had sold his business which apparently had realised good profits. But his successor very soon saw that by selling drugs and medicines at the same prices as his predecessor, he would soon be on the brink of ruin. He then discovered that the vendor of the business while copying all prescriptions accurately into his register, in accordance with the law, gave his customers very different preparations which, according to him, would produce the same effect as those ordered in the prescriptions, but were naturally much cheaper. At other times, when, for instance, the drug ordered had a very characteristic odour, he simply reduced the dose. He was in the habit of replacing salophen by antipyrine, glycerophosphates by ordinary phosphates, syrup of ipecacuanha by some emetic solution coloured to look like the real thing, while all mineral waters sold were manufactured in the shop. In defence he stated that some of these substitutes were made by his assistant without his knowledge, and as for others his customers had asked for them so that they might have less to pay. The tribunal awarded a heavy punishment, but allowed an appeal which will come up before the court shortly.

The Bicycle in the Treatment of Hernia.

At the meeting of the Academy of Medicine held on Jan. 31st M. Lucas Championnière read a paper by M. Loir, the director of the Pasteur Institute at Tunis, upon the treatment of hernia by means of a bicycle. M. Loir recounted the history of a patient who for four years had suffered from an inguinal hernia and who had tried various trusses without success. He tried bicycle riding, but at first because he used too high a machine the hernia slipped out under the truss. He then got a low machine and was astonished to find that the hernia became reduced when he got on. After four months his hernia had disappeared altogether. M. Loir considers this case unique, but as a matter of fact it is not so. Some ten years ago Dr. Oscar Jennings, in his work on "The Influence of the Tricycle on the Health," had noted the happy results on hernia of tricycle riding. For some time past M. Lucas Championnière has considered that the rest usually prescribed for those suffering from hernia is worse for them than muscular efforts. All workers suffer far less from a hernia than those who lead inactive lives, grow fat, suffer from cough, and get into a saddle with difficulty. M. Lucas Championnière related a case in which the use of a tricycle made two irreducible hernias quite comfortable to a patient in whom formerly they had given rise to various discomforts both local and general. Of course, to obtain a favourable result certain precautions must be observed. A rider with hernia must have his saddle low and placed far back; he must not ride too fast and must avoid hills. The use of the bicycle is an excellent way of consolidating the scar at the site of operation on a hernia and may be prescribed with advantage as soon as the patient is well enough to get about.

The German Malaria Commission.

THE official report of the German Commission for the Study of Malaria in Italy, under the presidency of Professor Koch, has been published in last week's number of the *Deutsche Medicinische Wochenschrift.* The Commission was directed (1) to study the so-called "febbri malariche estivo-autunnali"; (2) to ascertain the relations between Italian and tropical malaria; and (3) to study the mode of infection, especially by insects. The work of the Commission was accomplished partly in Milan and partly in Rome, where an abundant supply of cases was at its disposal. It was found that the "febbri estivoautunnali," though presenting clinical differences, were, from an etiological point of view, caused by one and the same well-characterised parasite. Recent cases showed the tertian type which in course of time became altered by the use of quinine or by natural immunity. The parasites of Italian and tropical malaria are identical, the differences alleged by Italian physicians to exist between them being based upon differences in the methods of investigation. The Commission farther ascertained that the semilunar form of the parasites was not caused by a degeneration as it contained chromatin, a certain symptom of a still existing capacity for propagation. A parasite very similar to that of the human subject was discovered in birds [illegible] the proteosoma which has been [illegible] ajor Ross," Indian Medical [illegible] 's opinion as to verified. From the resemblance between the two parasites it is very likely that the parasite of malaria develops in the same way as the proteosoma. During their stay in Rome the Commissioners had ample opportunity of observing the local and seasonal conditions of malaria. The city of Rome, though situated in a malarial district, is itself almost free from the disease. The cause of this very remarkable fact is not in the air which on all sides enters the town freely from the infected Campagna, neither is it in the water which is conveyed partly in open aqueducts from those districts, nor is it in the food which for the greater part is imported from the neighbourhood. The main difference between the conditions present in Rome and the surrounding country is that the interior of the city has no vegetation and therefore no mosquitoes. In winter the number of cases of malaria in the Roman hospitals is very small; in spring some cases of tertian fever are usually met with, whilst in June the number of patients increases suddenly and enormously. The cause of the prevalence of malaria in that month is not known. Methylene blue was successfully given in some cases in Italy and also in Berlin in tropical malaria when quinine was contraindicated by the simultaneous occurrence of blackwater fever. The "ticks" by which Texas fever is conveyed in East Africa were also discovered in cattle of the Campagna affected with Texas fever.

New Chemical Products as Medicines.

At a recent meeting of the Leipsic Medical Society Professor His drew attention to some disadvantages connected with the great development of chemical industry. He said that the interests of chemical manufacturers were not always in accordance with those of the public and the medical profession, for they produce every year an enormous number of new compounds which are forthwith placed on the market as therapeutical agents and they are anxious to sell as much as possible of each of them before a better one is issued by a trade rival. There is now scarcely a day that practitioners are not importuned by advertisements and samples sent to them and nearly every one of the new drugs is accompanied by the certificates of medical men stating that it is of incomparable value in certain diseases, but if inquiries are made after the lapse of a year or two one is surprised to find that the name of the once-vaunted remedy is scarcely known to the medical profession. The great majority of new compounds are nowadays recommended before they have been sufficiently proved as to their action and even their freedom from danger, one result of which was that so strongly toxic a substance as pyrodin was used as an antirheumatic and antipyretic remedy, not less than eight physicians having published articles favourable to the use of pyrodin, a substance which, according to Professor Liebreich, the eminent pharmacologist, has an extremely deleterious action on the blood. An exhaustive examination of new drugs ought to be made before their public sale is allowed. It is a fundamental maxim that new compounds ought first to be tried on animals by experienced pharmacologists. Some of the principal manufacturing chemists have already met this requirement by appointing pharmacologists of reputation and by providing them with well-equipped laboratories. The investigations conducted by the Elberfeld Farben Fabriken might serve as an example to other manufacturing firms. It is very undesirable that such investigations should be undertaken by inexperienced persons as the medical profession might in that case perhaps be misled by a mere similitude of scientific work. Experimental pharmacology affords a means of verifying the indications for the use of a new remedy and of ascertaining its possibly toxic action, but in order to discover its therapeutic effect it is necessary at last to try it on the human subject. Not everyone, however, is justified in administering new compounds to patients. Active substances ought to be tested only in hospitals where constant observation of the patients is possible, and where medical aid is at hand in the event of toxic symptoms manifesting themselves. Professor His then explained that the action of remedies could be verified either empirically or by the statistical method or the "rational" method and that the three methods must be used together. The conditions of rational research are very much improved by the use of modern methods of precision, such as the determination of weight, temperature, and blood-pressure, as well as by skiagraphy, auscultation, percussion, &c. In this way it is possible to avoid the complication of suggestion which is an important source of error. Apparent successes in treatment were often the effect of suggestion merely, instances of this kind being the results obtained by tuberculin, by suspension in tabes dorsalis, by electricity, &c. Professor His was of opinion that much experience and knowledge, combined with the critical faculty, are essential for those who would undertake the examination of pharmacological products, and men who do not possess these qualities had better abstain from therapeutical experiments or else keep their successes secret as long as possible. In medicine it often happens that it is the *cunctator* who gains the final victory.

The German Congress of Internal Medicine.

The German Congress of Internal Medicine will be held this year outside the boundaries of the German Empire in the famous Bohemian watering place of Carlsbad, under the presidency of Professor Quinke of Kiel. The official items on the programme are: (1) The Insufficiency of the Heart Muscles (to be introduced by Professor Schrötter of Vienna and Professor Martius of Rostock); and (2) Leukæmia and Leucocytosis (to be introduced by Professor Lowitt of Innsbruck and Professor Minkowski of Strassburg). Addresses will also be delivered on the following subjects:—Diagnosis and Treatment of Aneurysms of the Aorta, by Dr. Schmidt of Frankfort; Etiology of Syphilis According to Modern Researches, by Dr. von Niessen of Wiesbaden; Experiments on the Treatment of Tetanus, by Dr. Jacob of Berlin; Pathology of Gall-stones, by Dr. Meyer of Carlsbad; Treatment of Chronic Diseases of the Heart in Young Persons, by Dr. Schott of Nauheim; Administration of Digitalis in Troubles of the Circulation, by Dr. Groedel of Nauheim. Other addresses will be delivered by Professor Nothnagel of Vienna, by Professor Naunyn of Strassburg, by Dr. Leichtenstern of Cologne, by Professor Ebstein of Göttingen, by Professor von Jaksch of Prague, &c. The congress will last from April 11th to the 14th. Medical men desiring to attend must apply to Herr von Mattoni at Carlsbad.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"*Laureomania.*"

THE malady is a real one—a form, indeed, of "megalomania" so pronounced and becoming so common as well-nigh to have won its way into medico-psychological classification and certainly to have come under the consideration of Parliament. The craving for academic distinction (for this is what it amounts to) can be gratified all too cheaply in Italy, which, with a population of some 31,000,000, has at least 20 universities, to say nothing of what in Germany are called "Hochschulen," like the Istituto di Studi Superiori in Florence and the Istituto Lombardo di Scienze e Lettere in Milan. Entry into the liberal professions being thus so easy other occupations in business, in manufacture, and even in the handicrafts are impoverished to the serious injury of these and to the disturbance of the social order. As to the professions themselves the prospects of a livelihood they offer to their members become yearly more desperate, such is the overcrowding of their ranks, such the pressure of competition. We have it on the authority of the Minister of Public Instruction himself that to qualify and to graduate in medicine is from first to last a matter of little over 300 Italian lire, or £12! And yet to possess a degree, to be an "avvocato" or a "medico" (otherwise "professore" in the provinces), is an object of ambition well-nigh morbid and annually ever more eagerly craved for. Signor Fusinato, a member of the Chamber of Deputies, has just handed in his "relazione" (report) on the subject and the most startling, not to say ominous, figures are put in evidence. From 1882 to 1896 there was an increase of 42 per 1000 in the number of "laureati" or graduates in one or other of the faculties. As the population in that period has augmented by 6·2 per 1000 it follows that the increase of graduates between 1882 and 1896 has been approximately seven times greater than the corresponding rise in the population. Coming to particulars, let me begin with law. This profession has 8200 posts reserved for it in the public administrations and it has 10,000 members who practise it on their own account There are therefore 18 200 legal graduates more or less occupied The "waste or loss by death or "invalidità" (being pensioned off) in this *personnel* amounts to 500 annually, while the average production of graduates between 1832 and 1896 was 1070—that is, more than double the yearly loss Take our own profession For medical men there are reserved in the public administrations 20 757 posts, the average yearly "waste' is 500 and the average production of graduates per annum is 928—almost if not quite, double the number there is room for The pharmacists fare better For them there are 12 505 posts reserved The annual "waste is 313 and the production is 312 Veterinary surgeons in practice or in service are 2500 The annual "waste' is 63 and the production is 86 though it should be stated that out of 8257 communes only 1734 have hitherto provided themselves with "divisional' veterinary surgeons Midwives (for they too are "laureate') are in practice to the number of 10,243 Their 'waste is 256 and their production is 556 But here too, it should be said that 3338 communes have no 'levatrici condotte —that is hired or "divisional midwives Engineers also graduate in excess, there being every year 300 posts open to them, while annually 356 are 'laureati' Lastly come the graduates in philosophy and literature The posts reserved for them in the public administrations are 3371, there are about 100 of these open every year and there are 175 new graduates This excess of graduation is, as I have said, a grave evil making itself felt in a thousand pernicious ways As already pointed out in THE LANCET it explains the enormous number of what are conveniently called 'publicists or 'affaristi' in Italy—men whose business is agitation in the press or on the platform whose 'objective is 'place' and whose activity in the State serves no useful purpose while leaving commerce, industry, and even the humbler arts more and more short handed

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

The Victoria Branch of the British Medical Association

THE annual meeting of the Victoria Branch of the British Medical Association was held on Dec 21st 1898 From the report of the Council it appeared that 12 new members had joined during the year and district branches had been formed at Ballarat and Goulburn Valley The following were elected as office-bearers for the ensuing year President Mr A L Kenny, M B, vice president Mr G A Syme M S, F R C S honorary treasurer, Mr J R M Thomson M B, honorary secretary Mr W Kent Hughes M B Lond, M R C S Eng honorary librarian, Mr Felix Meyer, M B, editor of the *Australasian Medical Gazette* Mr J W Springthorpe M D Melb, M R C P Lond Members of Council Mr A V M Anderson M D, Mr I D Bird, M S M R C S, Mr I M Harricks, F R C S Irel, Mr H F Lawrence M R C P Edin, Mr R L McAdam, M D Dub Mr D McM Officer, M B, Mr M A O Sullivan, L R C S Irel Mr R R Stawell M D Melb Mr A W F Noyes F R C S Edin The retiring President Dr R L McAdam, read an address in which he congratulated the branch upon a very successful year of work, signalised further by the admission of lady members Reference was made to 'patent medicines and the necessity for taking steps to protect the community against these remedies and it was recommended that the Government should adopt the German custom of analysing these nostrums and having the result and the actual cost of each ingredient affixed to each bottle or packet The present methods of meat and milk supply came in for some scathing criticism The new Meat Bill was "a tardy effort to effect a much needed reform but "of still greater necessity was it that the milk supply of the community should be radically improved' The treatment of tuberculosis in sanatoria was next considered and it was pointed out that while the Victorian "climate was second to none in the facilities it afforded for taking advantage of the full benefit of the open air treatment yet there was in the colony no institution in which any attempt was made to carry it out in its completeness' It was estimated that in the comparatively small population of Victoria no less than 6000 phthisical subjects existed The death rate from phthisis was greater in Victoria than in any other of the Australasian colonies and it was higher than it had been It was strongly urged that an association should be formed for the prevention and treatment of phthisis Finally Dr McAdam referred to the relations between the medical profession and the friendly societies and said that whether remedies against existing evils were adopted or not rested entirely with the profession If its members presented a bold and united front they would obtain reasonable and fair treatment which was all they demanded The meeting closed with a hearty vote of thanks to Dr McAdam who afterwards entertained the members at supper

Outbreak of Anthrax in Sheep

A mob of sheep which arrived at the Melbourne saleyards from New South Wales was found by the inspector to be suffering from anthrax The inspector's opinion was confirmed by bacteriological examination by Dr Cherry at the Pathological Laboratory, Melbourne University Some of the sheep of the same mob had been sold as food before the disease was discovered Every precaution has been taken to prevent further infection

Insanity in New South Wales

The annual report of the Inspector General of the Insane for New South Wales shows that the number of insane is about 4000 of whom two in three are males 692 persons were admitted to the asylums and the net increase in patients was 112 which was less than in previous years The proportion of recoveries, 327 of the total number, is satisfactory, and nearly half the admissions were so far relieved as to be safely discharged to the care of friends The cost of maintenance in asylums was at the rate of £24 per patient annually and 13 per cent of the total cost of maintenance was contributed by the relatives of the patients As to causation, intemperance accounted for as many cases as were due to all the other causes The classes which gave the greatest number of patients were unskilled labourers, 149, domestic servants, 539, and persons of no occupation, 600

Opposition to the Children's Hospital at the Glebe Sydney

At a recent meeting of the Glebe Municipal Council a long discussion took place as to the desirability of allowing the Children's Hospital with its diphtheria wards to remain in so crowded a district and the following resolution was carried by six votes to two —

> That this Council is of opinion that the opening of the Diphtheria Hospital as a branch of the Children's Hospital in the Glebe is contrary to the expressed original intention when the Children's Hospital was opened that the existence of such Diphtheria Hospital in the Glebe is a menace to the health of the inhabitants and that the Government should be requested to immediately remove the same to some less crowded and more suitable locality

In opposition to the motion it was pointed out that out of 145 patients taken to the hospital from all parts of Sydney and the suburbs only 25 were fatal cases that not one of these was from the Glebe that only one death from diphtheria occurred in the Glebe outside the hospital, and that the objections to the hospital were purely sentimental

Food Standards in New South Wales

The Governor in Council of New South Wales has decreed, upon the recommendation of the Board of Health, the following food standards milk shall contain not less than 12 per cent of natural milk solids of which at least 3 2 parts must be genuine butter fat, butter must contain not less than 83 per cent genuine butter fat, tea must not contain more than 8 per cent of mineral matter calculated on the tea dried at 100° C of which at least 3 parts must be soluble in water, and the tea as sold must yield at least 28 per cent of extract vinegar should contain not less than 3 per cent of acetic acid and not more than a one thousandth part by weight of sulphuric acid

Death of the Secretary of the Melbourne Hospital

Mr J Williams who had been for 44 years secretary of the Melbourne Hospital and who resigned the position on Nov 29th 1898 owing to ill health died on Jan 3rd, 1899 He was the initiator of the Hospital Sunday collections in Melbourne in the year 1873, since when the total amount collected has been £57 000

Death of Dr A Mueller

Dr Augustus Mueller of Yackandandah died on Dec 31st 1898 He had practised in the district for over 40 years and was widely known as the originator of what has been called the "strychnine cure" for snake-bite. He was born in Westphalia in 1828 and graduated M.D. at Giessen in 1854. Besides practising his profession he was a *vigneron* of some note and was also a confirmed spiritualist. At the time of his death he was engaged in writing a work on the treatment of typhoid fever.

Jan. 3rd.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board in the subjects indicated:—

FIVE YEARS' REGULATIONS.

Part I. Chemistry and Physics.—Charles F. Medlicott Abbott-Brown, King's College, London; Owen Mortimer Bartlett, St. Mary's Hospital; Leonard Bolitho Bigg, St. Bartholomew's Hospital; George Birch, London Hospital; Lawrence Twemlow Booth, University College, Liverpool; Guy Leslie Buckeridge, Oxford University and Guy's Hospital; Thomas Waycott Chaff and Stephen Estridge Crawford, St. Bartholomew's Hospital; Arthur Frederick Cole and Harold Juler Cundell, St. Mary's Hospital; John Alfred Cronkshaw, Owens College, Manchester; Percy Toplis Drabble, Firth College, Sheffield; Armin Gascoigne Vavasour Elder, St. George's Hospital; Harry Loft Evans, St. Thomas's Hospital; Robert Marshall Fickling, Birkbeck Institute; Samuel Christopher Reeve Flaxman, Middlesex Hospital; Raymond Reynolds Garrett, St. Mary's Hospital; George Francis Hardy, Guy's Hospital; John Warwick Hele, Middlesex Hospital; Martin Herzheim, St. Bartholomew's Hospital; Ludovic Hill, St. Mungo's College, Glasgow; Nelson Wood Hill, London Hospital; Lionel Swinton Hooper, St. Thomas's Hospital; Hugh Morley Huggins, St. Bartholomew's Hospital; Sydney Francis Huth, St. Mary's Hospital; Edgar Norman Jupp, Guy's Hospital; Charles Samuel Kingston and Edward Leverton-Spry, St. Bartholomew's Hospital; Frederick Boulton Lowe, Guy's Hospital; Evelyn John Hausler Luxmoore, St. Mary's Hospital; Ernest Hammond McMahon, Charing-cross Hospital; Philip Jauvrin Marett, Westminster Hospital; George Boddy Messenger, University College, Liverpool; Hugh Francis Fountain Mortimer, Birkbeck Institute; Charles William O'Brien, St. Bartholomew's Hospital; Geoffrey Owens Parsons, St. Thomas's Hospital; Herbert Wilberforce Perkins, Birkbeck Institute; Bryan Pick, St. George's Hospital; James Derham Reid, Owens College, Manchester; David Harold Richards, Guy's Hospital; Thomas Rose, Middlesex Hospital; Edward John Henry Rudge and George Meredith Sanderson, London Hospital; Harvey Llewellyn Shelton, Guy's Hospital; Aaron Hoyland Smith, Firth College, Sheffield; Robert Spears and Howard Douglas Stewart, University College, London; Joseph Harvey Kemp Sykes, Yorkshire College, Leeds, and Technical College, Bradford; Francis Thompson, London Hospital; Edward Mervyn Thomson, St. George's Hospital; Henry Strawson Turner, King's College, London; Hugh Wheelwright, St. Thomas's Hospital; George Frederick Wilson, London Hospital; and Walter Frederick Wise, Middlesex Hospital.

48 gentlemen were referred for three months.

Part II. Practical Pharmacy.—Charles Birch, Mason University College, Birmingham; Sidney Charles Henry Bent, Guy's Hospital; Harry Hendy Butcher, St. Bartholomew's Hospital; Percival Butler, Private Study; William Reginald Cazenove and Joseph Taaffe De Coteau, Guy's Hospital; Thomas Waycott Chaff and Charles Dix, St. Bartholomew's Hospital; Walter Dick, University College, London; Reginald Ambrose Facey, St. Mary's Hospital; Harold Edwards Flint and Harold Goodman, St. Bartholomew's Hospital; Francisco José Gomez, King's College, London; Philip Lansdowne Hickes, University College, Bristol, and Guy's Hospital; Ludovic Hill, St. Mungo's College, Glasgow; Ricardo Luis Jimenez, Guy's Hospital; David John Lewis and James Adrian McComb, London Hospital; Leslie Miles Morris, St. Bartholomew's Hospital; Ridley Ewart Mounsey, St. George's Hospital; Samuel Northwood, Mason University College, Birmingham; Charles Louis Claude Owen, St. Bartholomew's Hospital; Horace George Pinches, St. Thomas's Hospital; Robert John Pritchard and William Owen Roberts, Guy's Hospital; Rees William Rees, Surgeons' Hall, Edinburgh, and University College, London; Edward Arthur Sanders, King's College, London; Robert West Stephenson, University College, Liverpool; George Shorland and Edwin John Tongue, Guy's Hospital; Arthur Ernest Whitehead, Firth College, Sheffield; and Henry Chadwick Woodcock, St. Mary's Hospital.

13 gentlemen were referred for three months.

Part III. Elementary Biology.—Harold Balme, King's College, London; Henry Bardsley, University College, Liverpool; Henry Stagg Bennett and Amelius Cyril Birt, St. Thomas's Hospital; Bertram Raleigh Bickford, Charing-cross Hospital; Sidney Clement Bowle, Guy's Hospital; Charles Reginald Bradley, Birkbeck Institute; Francis Arthur Brodribb, St. Paul's School, London; Hugh Donald Cochrane, St. Thomas's Hospital; Thomas Reginald Couldrey, St. Bartholomew's Hospital; Frederick Williams Crosswell, St. Mary's Hospital; Armin Gascoigne Vavasour Elder, St. George's Hospital; Harold Salter Gettings, Mason University College, Birmingham; Robert H. T. Penruddocke Harris and William Frederick Higginson, St. Mary's Hospital; Arthur Edgar Hay, King's College, London; John Warwick Hele, Middlesex Hospital; Arthur Stuart Menteith Hutchinson, and Alfred John Hopkinson Iles, St. Thomas's Hospital; Martin Herzheim and Robert Mackenzie Im Thurn, St. Bartholomew's Hospital; Marcus Antonius Johnston-Lavis, Epsom College; Seymour Whitworth Jones, St. Mary's Hospital; William Athol Desmond King, Middlesex Hospital; Colin Butterworth Lee, Owens College, Manchester; Paulin John Martin, St. Bartholomew's Hospital; Frederick James Pierce, Charing Cross Hospital; Edmund Arthur Roberts, King's College, London; James Derham Reid, Owens College, Manchester; Thomas Rose, Middlesex Hospital; George Meredith Sanderson and Samuel Smullan, London Hospital; Isaac Surtees Sheffield, Guy's Hospital; Malcolm Winfrid Shute, St. George's Hospital; George Morley Arundel Thomas, St. Mary's Hospital; Henry Strawson Turner, King's College, London; J. C. F. Dudley Vaughan, Bertram Joseph Wakley, Henry Albert Wickens West, and John Henry Marsden Whitehead, St. Thomas's Hospital; Arthur Reginald Wade, St. Bartholomew's Hospital; Salomon James Weinberg, Owens College, Manchester; Vernon Northwood Whitamore, Charing-cross Hospital; and Edwards Barton Cartwright White, London Hospital.

22 gentlemen were referred for three months.

FOUR YEARS' REGULATIONS.

Part II. Materia Medica.—Alexander Vigors Benson, London Hospital; George Minter Brown, Guy's Hospital; Augustus Charles Jenkins, London Hospital; Louis Charles Martin, Guy's Hospital; Peter Herbert Scholberg, Cambridge University and St. Bartholomew's Hospital; and William Peach Taylor, Firth College, Sheffield.

One gentleman was referred for three months.

Part III. Elementary Physiology.—James John Anning and James Ewing, Yorkshire College, Leeds.

UNIVERSITY OF LONDON.—The following candidates at the Intermediate Examination in Medicine held in January were successful:—

ENTIRE EXAMINATION.

First Division.—Archibald Douglas Hamilton, University College, Liverpool; Henry Walter James, University College, Cardiff, and St. Bartholomew's Hospital; and Philip Savill, University College.

Second Division.—Henry Martyn Brown, St. Mary's Hospital; Janet Mary Campbell, London School of Medicine for Women; Cecil Edwin Chriswick Child, Charing-cross Hospital, and Birkbeck Institute; Edward Murray Clarke, University College, Cardiff; Olive Claydon, London School of Medicine for Women; George Thomas Collins, Guy's Hospital; Lucian Arnold E. DeZilwa, B.Sc., University College; Henry Bertram Foster, Guy's Hospital; Lionel Capper Johnson, University College, Liverpool, and Owens College; Henry Crewe Keates, Guy's Hospital; Charles Ernest Lakin, Middlesex Hospital; Richard Ernest Lloyd, B.Sc., University College; Herbert Love, St. Bartholomew's Hospital; Frederick James Alexander Mayes, and John Sherwood New, University College; John Elliott Sparks, University College, Bristol; Louisa Spicer, London School of Medicine for Women; Albert Edward Thomas, St. Bartholomew's Hospital; and Vivian Francis Wall, St. Mary's Hospital.

The names of the other successful candidates, as well as of those who have passed the Preliminary Scientific Examination will be published next week.

UNIVERSITY OF CAMBRIDGE.—A Cambridge University Association has been formed for the purpose of enlarging the resources of the University, and, as we announced last week, the Chancellor, His Grace the Duke of Devonshire, is its President. In addition to a gift of £10,000 from the Chancellor and a like gift from Lord Rothschild's firm, benefactions amounting to over £30,000 have already been promised for specific objects. This includes the sum promised by the Drapers' Company for the establishment of a department of agricultural science. The following Bachelors of Arts were on Feb. 2nd admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery: F. H. Maturin, Gonville and Caius; G. E. Harthan, Jesus; A. E. Harrisson, Magdalene; and P. T. Sutcliffe and H. C. Thorp, Emmanuel.—A notice has been issued by the Special Board for Medicine giving a new schedule for the examination in Pharmaceutical Chemistry which forms part of the Second Examination for the degree of Bachelor of Medicine. This Schedule will come into force on the first day of October, 1899.

The examination will be practical and the questions set will have reference to—

(1) The chemical principles involved in the preparation of the following substances. reduced iron, mercury with chalk, lithium citrate, potassium iodide, mercurous chloride, mercuric chloride, calcium hypophosphite, arsenical (Fowler's) solution, hydrochloric solution of arsenic, sulphurated lime, iron phosphate, strong solution of ferric chloride, bismuth oxynitrate, strong solution of lead subacetate, tartarated antimony, iron and ammonium citrate, ammoniated mercury.

(2) The chemical relations characteristic of the following substances: solution of trinitrin, amyl nitrite, chloral hydrate, iodoform, hydrocyanic acid; the alkaloids atropine, brucine, codeine, morphine, quinine, strychnine, and caffeine; phenol, beta-naphthol, salicylic acid, salol; gallic acid, the tannins of galls and catechu; salicin; acetanilide, phenacetin, phenazone.

(3) The chemical incompatibilities of drugs as illustrated by the inter-action of iron salts with arsenical solutions, alkalies with mercurial preparations, acids with sulphurated lime, acids and oxidising agents with potassium iodide, and astringent solutions with alkaloids.

(4) The estimation by volumetric methods of arsenic and antimony in given solutions of chlorine in chlorinated lime, of hydrocyanic acid in cherry-laurel water and other solutions, of iron in reduced iron and iron phosphate, of nitrites in solution of ethyl nitrite and spirit of

nitrous ether and of citric and tartaric acid in given solutions standardised solutions being provided

(5) The characters of the foregoing substances and the physical and chemical tests for them and for their usual impurities.

FOREIGN UNIVERSITY INTELLIGENCE —*Bonn* Dr H Schroeder has been recognised as *privat docent* of Midwifery and Gynæcology —*Brussels* Dr Albert Crickx has been appointed *Professeur agrégé* —*Innsbruck* Dr Alois Lode has been appointed Extraordinary Professor of Hygiene —*Lausanne* Dr Combe *privat docent* of Pediatry has been promoted to an Extraordinary Professorship —*Marburg* Dr Eugen Enderlen has been recognised as *privat docent* in Surgery —*Munich* Dr J N Oeller has been appointed Extraordinary Professor of Ophthalmology —*Naples* Dr R Caporali has been recognised as *privat docent* of Medical Pathology Dr Fr Candia as *privat docent* of Gynæcology and Dr G Jacontini as *privat docent* of Medical Pathology —*Pavia* Dr Bernardino Silva has been promoted to the Ordinary Professorship of Medical Pathology Dr Scipione Riva Rocci of Turin has been recognised as *privat docent* of Medical Pathology —*Prague* Dr Eduard Nessel has been appointed Extraordinary Professor of Odontology —*Utrecht* Dr Snellen is about to retire from the chair of Ophthalmology

PRESENTATION TO A MEDICAL MAN —Mr A H Cook, M B L R C P Lond M R C S Eng of Roslyn hill Hampstead who has recently resigned the post of medical officer at the Hampstead Workhouse after 16 years service was the recipient on Jan. 28th of a handsome testimonial from his late colleagues

BATH EYE INFIRMARY —The annual meeting of governors and others interested in this institution was held on Jan 30th under the presidency of Mr H D Skrine The report showed that 208 in patients had been admitted during the past year, against 262 in 1897 Financially there was a good balance in hand and £245 the amount of legacies received had been carried to capital account

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH —The fifty ninth annual meeting of the subscribers of the South Devon and East Cornwall Hospital was held on Feb 3rd under the presidency of the Earl of Mount-Edgcumbe The report stated that 1313 in patients had been admitted during 1898 being 40 in excess of the previous year The out-patients treated were 2336 in number against 2445 in 1897 and 222 patients were sent to the convalescent home at Pearn which is in connexion with the hospital The financial statement showed that the expenditure for the year was £6509 and that there was an unfavourable balance of £416

BATH ROYAL UNITED HOSPITAL —The annual meeting of the governors and others interested in this institution was held at the Guildhall Bath on Jan 30th under the presidency of the mayor The report stated that during the year 1190 in patients had been treated against 1264 in 1897 a decrease of 74 The out-patients numbered 8209 being 779 less than in the preceding year During the past year the new chapel and kitchens had been constructed and the operation theatre refurnished The financial statement showed a falling off in subscriptions and donations but an increase in subscriptions from factories and workshops

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr August Socin Extraordinary Professor of Surgery in the University of Basle He was born at Vevey in 1837 and studied at Basle and Würzburg During the Franco-German War he was in charge of the Ambulance Hospital at Carlsruhe and subsequently published in conjunction with Professor E Klebs a work on the surgical cases which he had seen His chief subsequent publications related to the surgery of the urinary organs and especially to that of the prostate He was one of the editors of the *Beitrage zur Chirurgie* —Dr Giampaolo Vlacovich Professor of Anatomy in the University of Padua —Dr Karl Claus Professor of Zoology and Comparative Anatomy in the Philosophical Faculty of the University of Vienna —Dr Konstantinos Busakis Professor of Physiology in the University of Athens

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Opening of the Session

THE session of Parliament was opened by Royal Commission on Tuesday Feb 7th the session being the fifth of the present Parliament. As usual the Queen's Speech with which the session opened referred to the legislation proposed to be introduced by the Government Twelve Bills were mentioned four of them in separate paragraphs and the other eight in what is known as an omnibus paragraph Of the former the only one that need be noted here is a measure for the establishment of a board for the administration of primary secondary and technical education in England and Wales, and of the latter a Bill for providing a more complete distribution of water-supply in cases of emergency in London and a Bill for the prevention of the adulteration of articles of food Medical men will be disappointed to learn that the Speech made no reference whatever to the subject of revaccination and that neither the Marquis of Salisbury nor Mr Balfour mentioned it in their speeches in the Debate on the Address In connexion with India, the Queen's Speech said that the plague in that country still continues and though it has diminished in some districts previously affected it has spread to fresh places in Southern and Northern India and the remark was added that unremitting efforts continue to be made to relieve sufferers from the disease to check its spread in India and to prevent its transmission to other lands

The Vaccination Question

Mr BARTLEY has given notice that he will move for the preparation and issue of a return showing the number of persons who from the passing of the Vaccination Act of last year up to Dec 31st have under Section 2 of the Act satisfied two justices or a stipendiary or metropolitan police magistrate in petty sessions that they conscientiously believe that vaccination would be prejudicial to the health of their children the return to distinguish between Parliamentary boroughs and divisions of counties

The Flash Point of Petroleum Oil

Mr URE, one of the members of the Select Committee on Petroleum intends during the debate on the Address to ask the House of Commons to adopt an amendment expressing regret that no reference is made in the Queen's Speech to any measure of legislation designed to give effect to the recommendation of the Select Committee that legislative restrictions should be placed on all petroleum oil which has a flash point under 100° F

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* ' TO THE EDITORS,' and not in any case to any gentleman who may be *supposed to be connected with the* Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub Editor '

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed " To the Manager*

We cannot undertake to return MSS not used

MANAGER S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol II of 1898, which was completed with the issue of Dec 31st, and the Title page to the Volume, were given in THE LANCET of Jan 7th

VOLUMES AND CASES

VOLUMES for the second half of the year 1898 are now ready Bound in cloth, gilt lettered, price 18*s* , carriage extra

Cases for binding the half year s numbers are also ready Cloth gilt lettered, price 2*s* by post 2*s* 6*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their *Office* 423 Strand W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) *do* not reach THE LANCET Offices, and consequently inquiries concerning missing copies &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET *Offices*

Subscribers by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

Subscriptions (which may commence at any time) are payable in advance

THE SLOCUM METHODS.

The *New York World* is not a nice paper. It is one of the papers whose recent developments far exceed in vulgarity and stupidity anything that Dickens ever imagined in his portraits of Mr. Jefferson Brick and that warlike person's employers; and not so long ago we learn from the current issue of "Sell's Dictionary of the World's Press," it was excluded from the Century Club of New York, as well as from the files of certain public libraries. The following effusion is printed in the New Year's day edition of this paper, and we reproduce it because it forms a good example of the way in which an unscrupulous management can prostitute a paper. Of course the article is an advertisement, but it is printed as though it were editorial matter, so that all connected with the issue of the paper are damaged in their reputation for truth and decency, for the thing has the appearance of being written by any of them upon editorial instruction.

> WALES' PHYSICIAN ON CONSUMPTION.
>
> *Sir William Broadbent says Consumption Is Contagious and Curable—Not Hereditary.*
>
> AGREES WITH SLOCUM METHODS.
>
> *At a Meeting in London the Prince of Wales' Physician Fully Confirms Dr. Slocum's Teachings on This Disease.*
>
> LONDON, Dec. 31st.—A meeting of the National Society for the Prevention of Consumption and Other Forms of Tuberculosis held at Marlborough House, Dec. 20, was presided over by the Prince of Wales and addressed by Lord Salisbury and Sir William Broadbent, Physician to the Prince of Wales.
>
> Dr. Broadbent adheres to the view that consumption is not a hereditary but a contagious disease, and is therefore curable by a treatment which will destroy the germs and build up the system.
>
> He thus agrees with Dr. Slocum in every particular and his address is a practical indorsement of the system of treatment followed out so successfully by this well-known American practitioner.
>
> Dr. Slocum felt sure, when he first announced his theory, based on scientific experiments and practice, that consumption is a germ disease and not a hereditary taint, that the whole medical world would in time acknowledge that he was right.
>
> In Sir William Broadbent Dr. Slocum has an ally who will be of great assistance in teaching the people the real nature of consumption, its prevention and its cure.
>
> The first thing necessary, as these two great physicians show, is the killing of the germs of the disease and then the strengthening and building up of the system.
>
> This is just the system upon which the Dr. Slocum New Treatment for Consumption, Lung Weakness, and the Grip is based. *The germs of consumption, grip, &c.*

The article ends by recommending any one suffering from a wasting chronic complaint to call at the Doctor Slocum Laboratories, 98, Pine-street, New York. We have recently had in our articles upon "Quacks and Abortion" to comment very severely upon the laxity which allowed the management of many English journals to accept the dirty money of the persons who advertise remedies for "Female Obstructions of Whatever Kind," but at any rate these things were frankly advertisements. The claims as to the efficacy of the nostrums were made by the proprietors of the recipes and bore no appearance of being put forward editorially. Here, in the specimen of advertisement which we have given, the influence of the *New York World* is thrown into the scale on the side of the quack. This is a very different position and one which we venture to hope will never be taken up by any considerable or important section of the British press. There are papers published in London which make no secret of their animosity to the medical profession, but even when certain of them were placing before their readers the disgusting offers of Madame Frain, Lady Montrose, and the other advertisers of the same kidney, they one and all abstained from backing up the quackery to which they gave publicity by editorial pronouncements, spontaneous or purchased. But while we are thanking God that our papers are not as this American paper, let us not forget that until recent events scared or shamed them from earning ill-gotten gains, many of our journals were in receipt of large and regular sums from persons who were either abortion-mongers or obtainers of money upon false pretences or both. This situation must not arise again and medical men should be particularly concerned in ensuring this. Therefore if our readers see a suspicious advertisement in their local papers, or any advertisement of the most perfect superficial innocence but emanating from one of the quacks whom we have recently exposed, we hope they will send us a marked copy of the paper that we may take the proper steps.

HOMES FOR EPILEPTICS.

J. E. N.—Our correspondent might apply to the Meath Home of Comfort, Westbrook, Godalming. There is also the Colony for Epileptics at Chalfont St. Peter, the London offices of which are at 12, Buckingham-street, W.C.

THE DISPENSING FATALITY AT STOCKPORT.

In this case a patient died after taking a dose of a medicine dispensed by an unqualified dispenser upon, we must say, a most carelessly given prescription. The prescription in question was partly verbal and partly written. The dispenser at the inquest said that "morphia a drachm and a half" was ordered. The prescriber had meant solution of morphia but the dispenser took it to mean the pure alkaloid or its salt. He however only put in 30 grains because he had no more. Mr. Glyn-Jones, a member of the Pharmaceutical Society, has written to us "to emphasise the need for requiring a legal qualification from those engaged in the dispensing of poisons, whether in doctors' surgeries or chemists' shops. It may not be expedient to adopt the continental system by which doctors are not allowed to dispense their own medicines, but it ought to be easy to enact that the assistant employed by the doctor to dispense should be either a legally qualified medical man or a chemist. Such an enactment would be not only in the public interest, but would also work greatly to the advantage of the medical profession. It would be difficult to run cheap dispensaries if qualified dispensers had to be employed. If it was required that the dispenser employed should have a legal qualification the demand for qualified medical assistants would be considerably augmented. Apart, however, from the interests of the prescriber and dispenser there can be no doubt that the public are entitled to have their medicines dispensed by efficient assistants and to know that such efficiency has been vouched for by a legal qualification." We think Mr. Glyn-Jones's suggestion is a wise one. The unqualified dispenser is almost as dangerous as the unqualified medical man.

BODILY EXERCISE.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers tell me of a recent work on the physiology of bodily exercise or the therapeutics of exercise, or a work bearing on this subject?

I am, Sirs, yours faithfully,

N. H.

Jan. 23rd, 1899.

P.S.—I have read Lagrange's work.

*** The subject is dealt with in "The Elements of Physical Education," by David Lennox, M.D., and Alexander Sturrock. Blackwood. 4s.—ED. L.

"THE STYLE OF PHYSICIAN."

To the Editors of THE LANCET.

SIRS,—As a Doctor of Medicine without a diploma from a College of Physicians I have always held I should be wrong to term myself a "physician," and in the witness-box have denied when asked or it has been suggested that I am one. I should like to be informed whether that attitude is correct and if I should permit myself as now to be called a consulting physician (what other designation would do?) to an institution. *It seems to me the only persons who can properly term themselves* "physicians" are those who possess a College of Physicians diploma and that anyone else using that title is deceiving the public and could be proceeded against for illegal assumption of a diploma. I may be wrong and am open to conviction and wish to know whether a Doctor of Medicine only is legally a physician.

I am, Sirs, yours faithfully,

S. H.

Jan. 31st, 1899.

THE CASE OF WICKHAM *v.* PAYNE.

In this case recently tried in the Probate Division the plaintiff, Mrs. Wickham, claimed revocation of the will of her brother, alleging that the residuary clause had been obtained by the undue influence of the defendant's husband, Mr. Frank Cobham Payne. Mrs. Wickham's brother was a Dr. Tonkin and Mr. Payne is also a medical man. We need not go into all the allegations made by Mrs. Wickham for they were of a most disgraceful nature, but we will only say that the jury (the plaintiff's counsel having withdrawn from the case) found for the defendant—that is to say, they found practically that Mr. Payne was perfectly innocent of all the horrible crimes attributed to him although the legal defendant was his wife. We heartily congratulate Mr. Payne upon the result of the trial.

DOES ASPIRATION OF AIR THROUGH CHLOROFORM RENDER IT INERT AS AN ANÆSTHETIC?

To the Editors of THE LANCET.

SIRS,—When using a Krohne and Sesemann inhaler I find that it is practically impossible to get a patient under the influence of chloroform which has previously been used, it having had a large amount of air pumped through it. We say So-and-so has only taken two drachms of $CHCl_3$ during the operation, but it will be found that the remainder of the chloroform left in the bottle is practically, if not wholly, inert. At least, that has been my experience and I would like to hear if it has been the experience of anyone else. Is this failure of the anæsthetic due to (*a*) the impurities which have been pumped into it from the air or (*b*) has the chloroform become chemically altered by the same agency? A chemical analysis would clear up this latter point. Is there anyone who will undertake it? Thanking you for inserting this.

I am, Sirs, yours faithfully,

J. AUSTIN BRAITHWAITE.

Tynemouth Hospital, Dec. 2nd, 1898.

*** We have consulted many of those who employ Junker's inhaler (Messrs. Krohne and Sesemann's pattern) and find they have not observed any change in the chloroform after use. The tests given in the British Pharmacopœia, 1895 edition, p 75 will demonstrate any impurities in the chloroform employed. These tests are easily performed, but if they do not satisfy Mr. Braithwaite we suggest he should collect his residues after several operations, and when he has obtained some ounces he should send them to the original makers of the chloroform which he uses and request their chemists to report upon the sample If he will send us such residues we will analyse them for him with pleasure Good chloroform we need hardly say, should not undergo any change after air is pumped through it.—ED L.

THE APPOINTMENT OF PUBLIC VACCINATORS: AN ETHICAL QUESTION

WE publish these letters at the request of Mr Mackenzie and on the whole believe it may be for the good of the profession that such subjects should be publicly discussed:—

Foulby Wakefield, Dec 2nd, 1898

DEAR MACKENZIE,—Would you have any strong objection to my applying to the guardians for the public vaccinations in Crofton and Sharlston? The population of Crofton is three or four times greater than it used to be, and Sharlston also is considerably increased. The two would make one good district which might be sanctioned by the L G B

I am very busy, otherwise I would come over and see you about it Give us young uns a chance!

Yours very truly

J M HERMON

Normanton, Dec. 4th 1898

DEAR HERMON,—Thanks for letter of 4th I shall have a very strong objection on personal as well as professional grounds Have you seen the L G B Order? It proposes entirely new duties for public vaccinators of a police nature and they are going to give us 1s for what the ordinary "bobby" would get at least 3s 6d

We public vaccinators are now struggling to improve this, not only for our own sakes but for those that come after us and for any outsider to apply for any part of our appointments at this crisis would, to say the least, be scandalous and most of the profession would look at it as infamous—and you may be *quite sure* if any man comes between me and the guardians he will have a warm time of it Yours sincerely,

W S MACKENZIE

P S —I shall be delighted to see you at any time and open your eyes on the subject

Foulby, Wakefield, Dec 13th, 1898

DEAR MACKENZIE,—I have asked the opinion of some of my neighbouring medical friends about the vaccination question and all have agreed that considering that I live in one of the parishes in question and attend probably nine out of every 10 families in the other and have lived here for five years already I am not doing anything either scandalous or infamous nor unprofessional, I therefore intend to apply to the guardians and in doing so I feel that in one respect I am like you—viz, I am making the application not so much for myself as for whoever may follow me in work here, as it seems unlikely and unfair that the whole of Crofton shall have its public vaccinator living at Normanton, more than four miles away I thought it better to tell you this as until hearing the opinions mentioned I had given up the thought of applying Meantime yours very truly

J M. HERMON

The Orchard Normanton, Dec. 17th 1898

DEAR HERMON,—On returning from a short holiday I find yours of 13th Do you mean to say you have submitted to medical friends the question whether you are or are not to apply for an appointment which I have held for about 20 years, which I hold now, and have no intention of resigning, and that they approve of your applying for it? No medical man in this district will dare to say so to me in front of his medical neighbours.

They must have been *pulling your leg* I never heard of anything more unprofessional and intend to publish the correspondence but will wait a few days for your reply

Your plea that it is not f r th t Cro ton should have its public vaccinator four miles aw y is too ridiculous, the few minutes it takes me to go to Crofton i no great tax upon any man's time as long as he is willing An it is all the same to Crofton people where the public va cinato l es Yours faithfully,

Dr Hermon, Foulby W S MACKENZIE.

Foulby, Wakefield, Dec. 20th 1898

DEAR MACKENZIE,—I understand that at the next meeting probably of the guardians th wh le question of vaccination districts is to be considered so I w ll n t find it necessary to make a direct application

I should imagine that the *personal* objection weighs with you more than the *p o e sional* one but the whole tone of both your letters is of such a bullying nature that I cannot take them as being seriously meant I think your letters would not look well in print, but you can print them if you like I have no objection

Yours very truly,

J M HERMON

P S —Of the medical men I consulted two are Public Vaccinators

The *Wakefield Express* of Jan 7th contains a report of the meeting of the Wakefield Board of Guardians at which a le er was read from Dr Hermon offering his services as public vaccinator for Crofton and Sharlston and suggesting the formation of a new district, so that Dr Hermon has evidently reconsidered his decision that he would not find it necessary to make his application directly We think it unfortunate under any circumstances for a medical man to seek a post which is held by another medical man and therefore regret that Dr. Hermon should have made his application, to which, by the way, the board of guardians, instructed by their clerk, found that they were unable to accede We would at the same time point out that Dr Hermon informed Mr Mackenzie of his wishes before making the application, so that the element of secrecy which we have had several times to condemn strongly is absent in this case Again, Mr Mackenzie's tone in his letters is unfortunate, so much so that we can understand Dr Hermon's inclinations running rather towards disobeying than towards obeying the wishes of his senior *confrère*

THE REICHARDT FUND

To the Editors of THE LANCET

SIRS,—Dr Goodhart and I have to acknowledge the receipt of the following contributions on behalf of this fund We beg to remind the very many members of the profession who are interested in the home treatment of mental disorders that very few have so far contributed in aid of this fund I am, Sirs, yours faithfully,

3, Henrietta street, W, Feb 6th 1899 GEO H SAVAGE

◆

Cottage —So far from the action being unprofessional it *may* be almost a professional duty We speak from the facts supplied, we do not know the population of the district or how far other medical men may be affected, or what arrangements it is proposed to make for an honorary medical staff

Querist —(1) A medical man should not act in consultation with an unqualified person under any circumstances or attend cases where such a person is in any way responsible for the treatment, (2) THE LANCET, April 4th, 1896, p. 961

L.R C S Edin —The fares are paid of gentlemen who come on approval If an assistant accepts an offer of engagement we do not think it is usual to pay him his travelling expenses

L.F C P, &c —"Psycho therapeutics" by Dr C Lloyd Tuckey, and "The Practice of Hypnotic Suggestion," by Dr G C Kingsbury, might be consulted

C S, M D —Certainly the letter is in very poor taste But we think it preferable not to notice it.

The Hunterian Oration.

Delivered at the Royal College of Surgeons of England on Feb. 14th, 1899,

By SIR WILLIAM MAC CORMAC, Bart.,
K.C.V.O., F.R.C.S. Eng. and Irel.,
SURGEON IN-ORDINARY TO HIS ROYAL HIGHNESS THE PRINCE OF WALES; KNIGHT OF GRACE, ORDER OF ST JOHN OF JERUSALEM; PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, CONSULTING SURGEON AND EMERITUS LECTURER ON CLINICAL SURGERY, ST. THOMAS'S HOSPITAL; CONSULTING SURGEON QUEEN CHARLOTTE'S HOSPITAL, FRENCH HOSPITAL, ITALIAN HOSPITAL, BRITISH LYING-IN HOSPITAL, AND ROYAL HOSPITAL, BELFAST.

Your Royal Highness, My Lords and Gentlemen,—In accordance with the terms of a deed establishing the Hunterian Oration we celebrate to-day John Hunter's name and fame. Born on Feb. 14th in the year 1728 at Long Calderwood, a small estate his father farmed, some eight miles from Glasgow, he died on Oct. 16th, 1793, in his sixty-fifth year, celebrated alike as a great surgeon, a profound biologist, and a man of genius. It is fitting that this College, the heir to Hunter's great collection, should take care for his memory, and one way in which this is done, however inadequately, is by means of the Hunterian Oration, delivered in this theatre in alternate years. Here, in view of this noble presentment of Hunter by the foremost painter of his time, the orator is called upon to praise its foremost surgeon. Hunter was a bad sitter and it was almost by an accident that Reynolds obtained the opportunity to paint this, one of his finest portraits. In the background are indicated the bones of O'Brien the Giant whom Hunter affectionately calls his "tall man," a preparation showing the vessels of the heart suggestive of his work on aneurysm, and three volumes of his manuscript notes. As we look at the picture, painted in 1785, when Hunter was 57 years old, we perceive him in deep reverie in one of those waking dreams to which he refers in his *lectures. He has* paused from writing in order to think out some problem and, as he often said, it was a delight to him to think. As we dwell upon the features we cannot doubt that a sudden inspiration has flashed upon and gradually pervaded his mind, some great scientific truth or generalisation which he has grasped and is pondering with intense satisfaction. Those eyes, full of the keenest intelligence, seem in eager quest of something far beyond the visible tokens of his work. We may imagine Hunter trying, perchance, to solve some hidden mystery of life or seeking to pierce the veil which hides from us the great unknown beyond. Buckle calls Hunter a genius whose only fault was an occasional obscurity in language and in thought. "It sometimes seems," he writes in his "History of Civilisation," "as if Hunter's understanding were troubled by the grandeur of its own conceptions and doubted the path it ought to take. Still, his powers were so extraordinary that among the great masters of organic science he belongs to the same rank as Aristotle, Harvey, and Bichat and is somewhat superior to Haller and Cuvier."

Early Life.

What, then, was the manner of man whom Buckle thus characterises? I would desire to present him to you as a yet surviving influence, to recall his very words, and to show him to you as he lived. To appreciate or even fully to comprehend the labours of Hunter one must strive to judge them from the standpoint of his time, for in this way only can we form a just conception of their splendid superiority. On Hunter's early life and the many moot points it involves—his preliminary education or the want of it, whether he was for a time a carpenter by trade, why he was not sent to learn the humanities at Glasgow College like his brothers, or why in later life he spent some time at Oxford University[1] without any apparent appreciation of the academic learning there offered to him—I do not propose to dwell. John Hunter was the youngest child of a family of 10 and the spoiled son of his mother. As a boy his pleasure was to ramble in the quiet woodlands, observe the ways of the living things he found there, collect the eggs of birds and compare them together. "I wanted to know," he tells us, "all about the clouds and the grasses and why the leaves change colour in the autumn; I watched the ants, bees, birds, tadpoles, and caddis-worms; I pestered people with questions about what nobody knew or cared anything about." Hunter's scientific career dates from his arrival in London in 1748 where, when 20 years of age, he joined his brother William's school as an ill-educated youth, new to all the amenities of life, brusque in manner and negligent in appearance, yet with a keen sense of physical enjoyment. As a pupil he showed a marvellous aptitude for anatomy and soon became a successful teacher of it, but he always remained a learner in that great book of nature which was ever open before him and whose pages, until he died 45 years later, he never ceased to turn, interpreting aright many of its obscurest passages.

It was thus that Hunter started on a career destined to mark deeply the history of his time. From the moment he began to work his industry was never-ceasing, his patience was extraordinary, and his capacity for unflagging effort was so sustained that it brought him step by step to a position which has earned for him the praise and admiration of his successors. In 1759, undermined in health by 10 years of incessant toil, he contracted an attack of pneumonia and his weakened constitution was threatened with phthisis. Recommended to take rest, he only changed one sphere of activity for another, and having obtained through his brother's influence an appointment as surgeon in the army he sailed (1761) with Keppel for Belle-Isle and afterwards accompanied the expedition into Portugal. It was there that he studied the phases of inflammation and the treatment of gunshot wounds. When he returned to London after peace was proclaimed (1763), with nothing but his half-pay to provide the wherewithal to live upon and nothing but his genius to trust to for advancement, Hunter's life became an extremely arduous one. He was able to do with little sleep, and from four or five in the morning until the breakfast hour he dissected, then he saw patients, visited the hospital, pursued his researches, worked at his note-books, and pondered the bearing of his observations till midnight. He was elected a Fellow of the Royal Society when 39 years of age, a year later became surgeon to St. George's Hospital, and in 177[illegible] was appointed surgeon-extraordinary to the King. In 1786 he was appointed deputy-surgeon-general [illegible] army and three years later became surgeon-general. He also published his work on Venereal Diseases in 1786 and the following year received the Copley Medal from the Royal Society on account of many valuable papers. His great work on the "Blood and Inflammation," however, still remained unfinished after thirty years of labour bestowed upon it and was only published after his death. At 50 years of age he had reached the zenith of his surgical career, having done more to improve the science of surgery than all the other surgeons of Europe had done before him. When Pott died Hunter became the chief surgical authority in London; his opinion was highly valued in all difficult cases and he acquired a lucrative practice. There is no doubt that he was an admirable clinical teacher and a courageous operator, and although his systematic lectures on surgery were marred by a faulty delivery and occasional obscurity of style they attracted all those who afterwards attained distinction amongst their contemporaries.

Lecturer and Collector.

Cline was 24 years of age when he attended Hunter's first course of lectures and they must have deeply impressed him, for he says that "although well acquainted with the opinions of the most distinguished surgeons then practising in London he found Mr. Hunter's lectures so far superior to anything he had conceived or heard before that there seemed no comparison between the great mind of the man who delivered them and all the individuals, whether ancient or modern, who had gone before him." We only possess an account circumscribed, not diffusing itself gradually and imperceptibly into the surrounding parts but terminating rather abruptly. Its base is hard and its edges a little prominent." A description which leaves little to be desired in the way of precision and accuracy.

---

[1] At the outset of his career in London William Hunter desired that his brother John should be trained as a physician and sent him to Oxford to obtain the necessary classical education, but during the short period he spent there he found himself quite unable to study Latin and Greek and spoke afterwards rather contemptuously of the ancient learning. One might refer in illustration of this to what John Hunter remarked on one occasion of Jessé Foot, his spiteful biographer, who combines a very hostile criticism of everything Hunter said or did with acrid personal invective: "Jesse Foot accuses me of not knowing the dead languages but I could teach him that on the dead body which he never knew in any language, dead or living."

Hunter's observations in regard to gonorrhœa are clear-sighted and discriminating. He noticed that in the earlier stages of the malady the inflammation is restricted to the anterior portion of the urethra and that epididymitis is a late symptom. He observed that in gonorrhœa the vas may become obliterated, which he says will have no bad consequences if only one testicle be affected, as the other will *suffice* for all purposes. He thus anticipates the observations of Gosselin and Curling on aspermia from this cause.[2] Hunter describes the various forms of stricture in a graphic manner, points out that the bulbous portion of the urethra is more liable to the disorder than the whole of the urethra besides, and that *he never saw a stricture in the prostatic* portion of the urethra. He tells us that it happens generally, if not always, that gleet is associated with stricture and that this symptom often leads us to a knowledge of a stricture or at least affords a suspicion of its presence. In regard to treatment, he considers the cure of stricture can only be effected by local applications and that mercury has been given erroneously and without success. A surgeon should in general first make himself acquainted with the situation of the stricture by an ordinary-sized bougie and afterwards make use of a *smaller one*. Dilatation can be effected by the bougie but it is seldom more than a temporary cure. There is always remaining the original tendency to contraction and this recurs sooner or later.

His description of the use of bougies is full of practical interest. He mentions a new form as one of the greatest improvements in surgery and can scarcely persuade himself that in using it he is treating the same disease. He says: "When I was attending the first hospitals in this city in the year 1750 the common bougies were either a piece of lead or a small wax candle, and although the present bougie was then *known yet due preference* was not given to it nor its particular merit understood. A piece of the end of the leaden bougie sometimes broke off in the bladder and quicksilver was injected to dissolve it." There is in the [illegible] a series of bougies which belonged originally to Abernethy.[3] They are doubtless quite similar [illegible] copies of those to which Hunter alludes. His descriptions of the complications dependent on the presence of stricture are accurate and detailed. Extravasation of urine, perineal *fistula, false passage, abscess in* Cowper's glands, in the prostate, and peri-urethral abscess are fully described and dealt with. In treating of retention of urine, which he calls "suppression" he gives an account of tapping the bladder above the pubes through the rectum and by way of the perineum; he details the circumstances which, in his opinion, indicate the choice of method in a manner which could scarcely be improved in the pages of a modern text-book; and in describing perineal puncture of the bladder he goes very close indeed to the modern operations suggested by Sir John Simon and Mr. Wheelhouse.

INFLAMMATION.

Hunter dedicated his epoch-making treatise on the "Blood, Inflammation, and Gunshot Wounds" to the King and it is in many respects his most important work. It was planned after the reduction of Belleisle and the peace of 1763 upon the basis of notes and observations made during his 11 years' residence in London and on his experience of the inflammation that usually attended on gunshot wounds. In this work Hunter makes a bold attempt to enunciate the laws which govern life, not only in healthy but also in diseased conditions. He recognises that the *physiological* state of the organism does not pass abruptly into that of disease but by *a gradual transition*. No previous physiologist had adopted similar views and Hunter's clear insight into the processes at work in the animal body furnished a new departure in biological science, the value of his opinions being shown by the impression they produced upon every succeeding worker in the same field. Not only are the thoughts new but the language in which he formulates them had in many instances to be new also and was often, as might be expected, difficult to understand. Life he believed to exist in every part of the animal body susceptible of impressions which excite action. There is no part, he says, that does not possess more or less of this vital influence and the impressions thence arising produce infinite variety in all natural and diseased acts. "I cannot tell," he says, "*how far each part might possess* an equal quantity of life; but if we were to judge it by its power of action we should judge tolerably well. Disease would seem to give some intelligence with regard to this matter, but how far the resistance to disease and power of restoration depend on the power of life I cannot say. I believe it may be set down as a rule that those parts endowed with most action resist disease most strongly and in disease restore themselves most readily to a healthy state." This law has exceptions, yet it certainly applies in a large degree to all pathological changes. He regarded the blood as possessed of life like the more solid parts, and that it formed the bond of union between the structures divided in a wound. In what he calls "union by first intention" he recognised a process essentially different from that of inflammation. "In the adhesive inflammation," he says, "the vessels, being enlarged, begin to separate from the mass (of the blood) some portion of the coagulating lymph with some serum and also red globules, throw it out on the surface and cover the sides (of the wound) with cells, which easily unite with the opposite ones with which they are in contact, forming the first process of adhesion." He observed the vessels passing into and ramifying in the new material so that the vessel was plainly continued from the old into the new tissue. He further adds that "in many bruises as well as in simple fracture, where the cavities are not exposed, the inflammation in most of these cases is capable of being resolved. In parts which have been divided and exposed the inflammation is in a great measure controlled by bringing them together; or where parts are *not* brought together nature attempts to *prevent* inflammation by covering the wound with blood and forming an eschar. The adhesive inflammation serves as a check to the suppuration by making parts which would otherwise infallibly fall into that state previously unite in order to prevent its access."

The views and principles he thus formulated are essentially correct; they have served as a foundation for subsequent wide-reaching investigation and form the basis of subcutaneous surgery and the treatment of wounds which, *previously* kept open, *Hunter* sought to close. After describing what he terms "true suppuration" which he contends is the result of inflammation *only* he goes on to speak of swellings without the usual symptoms of inflammation often containing collections of *matter* resembling suppuration. He considers these collections to be scrofulous in nature, common in young subjects, rare in the full-grown or old. He thinks their contents are erroneously called "purulent." To this category he refers the slow swelling of joints and of lymphatic glands, the scrofulous enlargements and suppurations of the knee, the foot, and the ankle. He completely differentiates the breaking down of a tuberculous deposit from true suppuration occurring in the course of simple inflammation. He calls attention to what he terms the "curdly substance" in the fluid, distinguishing it from true pus. He tells us these collections move easily from their original seat to some other part by slight pressure or their own weight. The migrating collection which descends from a carious vertebra to the groin he calls "an abscess in a part" in opposition to "an abscess of a part." Indeed, he gives the salient characters of these disorders with the keenest insight, and his descriptions suggest to me the masterly power of some great artist who with a few strokes of his pencil is able to indicate a powerful situation or suggest a *startling* action.

When we study Hunter's works we find many later views and advances foreshadowed. It is wonderful to *reflect on* how much he has seen and described; the correctness and depth of his observations, and his ability to utilise the experimental method. There is scarcely any branch of anatomical or physiological inquiry which he has not illumined and few subjects in either medicine or surgery which have not benefited by his researches. His remarks on the union of severed tendons were apparently suggested by the accidental rupture of one of his own and prompted Delpech many years afterwards (1816) to divide for the first time the Achilles tendon for pes equinus This proved the foundation of orthopædic surgery developed by Stromeyer and since his time. "Of cancer," he reminds us, "no cure has yet been found, for what I call cure is an alteration of the disposition and the effects of that disposition and not the destruction of the cancerous parts." And to-day we can only, alas, endorse what Hunter said. In that branch of surgery where we boast of our greatest and most recent advances Hunter's originality is seen in the new paths of practice he indicated. He advises opening and washing out the abdomen in suppurative peritonitis and points out how often adhesions form which prevent the otherwise fatal results of a perforated bowel. He writes that "tapping is but a palliative in ovarian dropsy. The tumour generally renders life disagreeable for a year or two and then kills in the end. There is no reason why women should not bear spaying as well as other animals. It would be simply opening the cavity of the abdomen which we often do without inconvenience." Yet the establishment of ovariotomy as a successful surgical operation was postponed until the present generation. Did time permit or the occasion demand it I might quote other examples of the wonderful foreknowledge of Hunter. From the high standpoint of his own learning he was able to grasp what was previously unknown and to utilise his discoveries for the common good both of science and of mankind.

---

[2] In the "Archives Générales de Médecine," 1847 and 1853, Gosselin contributed several papers on "Oblitération des Voies Spermatiques." In these he points out that the spermatic duct may become obliterated as the result of gonorrhœal epididymitis, that the obstruction may take place in the vas, the head of the epididymis, or in the seminiferous tubules. He states, erroneously however, that no previous author had noticed this fact and that the condition was one hitherto undescribed, the probable explanation being that there is no physiological change of function to attract notice during life and that it could only be discovered by a minute anatomical examination after death. He also shows that when both sides are affected the person must be sterile, as the absence of spermatozoa can be proved, although he will not be impotent. Curling in his work on the "Diseases of the Testicle," refers to the occasional occurrence of obstruction in the tail of the epididymis. He quotes Gosselin's investigations in 1853 which he fully corroborates. The inflammatory exudation, he says, in the walls and cavity of the ducts may cause their obliteration, generally in the globus minor, and when this is bilateral it will involve sterility.

[3] The Orator presented specimens of Hunter's form of bougie.

GUNSHOT WOUNDS.

John Hunter attached the greatest value to the experience he had gained while serving with the army. But little of real importance had been previously written on military surgery and the practice pursued had hardly been reduced to the common rules of surgery. We know, too, from the records of the time what imperfect education and training were accepted from those seeking admission to the public service, and that it was almost unnecessary for a man to be a surgeon to practise in the army.[4] Hunter writes: "A gunshot wound is often not understood at first. It may be impossible to tell what parts are implicated; a bone or large vessel may be contused or a viscus injured. A part of the intestine may have received a contusion so as to cause a slough, and on the slough becoming separated a new symptom will probably appear, for the contents of the intestines will come through the wound. But these cases will not be so dangerous as if the same loss had been produced at first, for by this time all communication will have been cut off. Nor will it be so dangerous as when a considerable blood-vessel is deadened, for in this case when the slough comes off, the blood getting a free passage into the wound, as also out of it, death will probably immediately follow." "Gunshot wounds," he goes on to say, "often do much mischief to vital parts and their effect will be according to whether the soundness of the part wounded is essential either to the health of the whole body or the uses of the part wounded, as an important viscus whose function is arrested or a large joint whose uses are impeded. Gunshot wounds often admit of being classed with small deep-seated wounds (punctured) which are always of a particular kind. Indeed, the variety of circumstances attending gunshot wounds is almost endless." He discusses the different effects resulting from the variable velocity of the projectile and the consequent differences in injuries of bone and of soft parts He speaks of the straight course and the keyhole punched out fracture produced in the bone by a bullet with great velocity and the devious tracks it may follow when travelling slowly. The wounds made by musket-balls in the wars of his time were very different from those produced by modern rifles whose small bullet may traverse the soft parts without doing them much damage while it pulverises the bone. The old flint lock propelling a large spherical bullet with a small velocity produced large contused or lacerated wounds of soft parts and splintered the bone.

There is no doubt that Hunter's work on gunshot wounds was a great step in the direction of their more rational treatment and laid the foundation of modern military surgery. "It has been hitherto recommended," he writes, "and universally practised by almost everyone, to enlarge the external orifice of gunshot wounds immediately on their being received, or as soon after as possible, and this without any discrimination between one gunshot wound and another." Hunter emphatically protests against this practice if only for the reason that few gunshot wounds are alike and the same practice cannot apply to all. "It is contrary," he urges, "to the rules of surgery as founded on our knowledge of the animal economy to enlarge wounds simply as wounds, for no wound, however small, should be enlarged unless something necessary is to be done which cannot be executed unless the wound be enlarged. This is common surgery and ought to be military surgery." Here his rare intelligence ran counter to generally received opinions and to the practice strongly inculcated by his illustrious predecessors, Ambroise Paré, Richard Wiseman, and Baron Percy. "It would be absurd, however," he continued, "for anyone to suppose that there is never occasion to dilate gunshot wounds at all, but it is certain that there are very few in which it is necessary." He tells us how seldom a wound need be dilated on account of the bullet itself; "balls when obliged to be left seldom do any harm when they are not in a vital part and have been known to lie in the body for years and yet the person has found no inconvenience." There can be little doubt of the soundness of this doctrine and it is certain that in very many instances greater injury has been inflicted in the unavailing search after the bullet or even in its extraction than the wound of itself could cause. Yet how persistently this superstition, I would call it, lingers in the public mind. The first anxiety of a man who is shot, soldier and civilian alike, is that the bullet, wherever lodged, should be forthwith extracted. The number and infinite variety of bullet-finders and [illegible] extractors which have been invented show that the art of bullet-hunting has flourished in spite of all that Hunter urged against it. "If the wound will admit it, the finger," he says, "is the best instrument to make exploration with," an opinion I heartily endorse, especially since the risks formerly attending its introduction may now be removed.

What would Hunter think of our improved methods of diagnosis or the discovery by the new photography of the exact position, amount of comminution and direction of a fracture, the locality of a foreign body, and the determination of the depth and relation to the surface of a lodged bullet, so that if for any reason it be deemed desirable to operate it may be cut down upon with almost as much precision as if the tissues covering it were translucent?

"What," he inquires, "is the very best practice where it is supposed the intestines may be wounded? I should suppose the very best practice is to be quiet and do nothing." How much therefore he would admire an exploratory operation for the discovery of a perforated intestine, the restoration of its continuity by one of the methods employed, the aseptic rendering of the abdominal cavity, and the frequent recovery of the patient without reaction, pain, inflammation, or any sort of complication. "Little notice," he tells us, "has been taken of wounds in the chest and lungs because it was assumed nothing could be done for them." "Yet I have seen," he says, "several cases of gunshot injury where the patient got well after being shot quite through the lungs." And our recent military experience proves how right Hunter was, since many persons whose lungs have been traversed by modern projectiles not only recover, but seem scarcely to suffer inconvenience from the injury either at the time or afterwards. Hunter differs, however, not only from those who preceded him, but from modern practice and opinion, in his advocacy of secondary in preference to primary amputation. He considers immediate amputation improper, as the surgeon cannot, under the circumstances, master the case adequately, and few amputations on the field of battle do well, "the only argument in their favour being that the wounded man is moved with greater ease without a limb than with a shattered one"; but I think it is now universally admitted that cases which demand amputation should be operated upon at the earliest period, either in the first dressing-station or the field hospitals, and that a delay of 24 hours or longer very seriously increases the risks.

---

[4] Smollett entered the navy in 1739 when he obtained the post of surgeon on a king's ship. In "Roderick Random" which was published in 1743 he described the life and character of the naval surgeon at that time and the life so described was a terrible one. Just 100 years later, 1848, Huxley entered Her Majesty's navy He was assistant surgeon to the *Rattlesnake* during her cruises off the northern and eastern coasts of Australia and the observations he then made formed material for his well known work on "Oceanic *Hydrozoa*." John MacGillivray was naturalist to the expedition, Huxley being what would have been formerly called a surgeon's mate The difference between Huxley and Smollett sufficiently emphasises the different condition of the public service at the present time and what obtained 100 years ago, when the captain of the ship, Smollett tells us, was too much of a gentleman to know a surgeon's mate even by sight.

While assuredly Hunter was far in advance of his predecessors in the teaching and practice of military surgery, in some instances to such a degree that his views would hold good to-day, yet the conditions of warfare have become so changed and gunshot wounds are so different that the surgery of the battlefield no less than that of civil life has been revolutionised. Hunter clearly recognised that the destructive effect of a bullet on animal tissues depends on its velocity rather than on its weight. This is the characteristic by which the modern small-bore bullet, with its cupro-nickel or steel envelope, differs so greatly from the round bullet of Hunter's day and on which those modifications of gunshot injuries which have taken place depend. The old round bullet produced at all ranges more severe wounds of the soft parts than the modern missile does, and at short ranges probably caused as extensive a fracture of a bone, but it so rapidly lost its energy that at distances of even a hundred yards it frequently flattened out against the shaft of a long bone without causing fracture. The modern bullet produces at almost all distances unimportant wounds of muscular tissue, but it is apt to cut pieces out of the large vessels, which render any hæmostatic process ineffective, and in consequence death from primary hæmorrhage on the battlefield will be far more frequent than before. Injuries to long bones by hard-mantled bullets produce, at ranges of over 2000 yards, tunnelling without any great fragmentation, while as the range decreases the extent of the fissuring, the number of the fragments, and the distance to which the latter are driven steadily increase, until at ranges under 300 yards the extensive damage and destruction on the exit side of the limb have all the appearance of being produced by a small-arm shell or explosive bullet. Gunshot fractures of the shaft and of the articular ends of the long bones were considered to demand immediate amputation in Hunter's day, a rule which permitted but few exceptions for military surgeons of former times. In modern surgery the rule, if any, tends the other passiv, and only in exceptional cases—those in which an injury is not confined to the bone and unimportant soft parts, but in which the main vessels and nerves are also implicated—are more radical procedures to be recommended. In consequence of the suppuration which formerly always occurred in these cases, the comminuted and displaced pieces of bone acting as foreign bodies had to be thrown off by nature's efforts, and consolidation of a fracture was often long delayed or did not take place at all, while cases treated conservatively usually died from surgical infective diseases. In recent campaigns gunshot fractures of the long bones, even when greatly comminuted, and penetrating injuries of joints have been treated by conservative methods with success, except in cases where the blood- and nerve-supplies of the limb below are cut off by laceration of the main trunks. Amputation is only resorted to when no other resource remains to the surgeon, and occasionally, perhaps, when military exigencies necessitate the immediate transference of the wounded to the base of operations, circumstances which render conservative treatment, at all events for injuries of the lower limb, either impossible or at least more dangerous than operation. No doubt some small percentage of cases of gunshot injury of long bones and of large joints did formerly recover without amputation; but it has only been since Listerian methods of treatment were perfected that conservative treatment in time of war on a large scale and as a rule has become possible to the military surgeon. That Hunter was the great military surgeon of his time may be seen both in his teaching and in his writings, and our opinion of his greatness must be enhanced when we remember the scanty means at his disposal for bringing his surgery to a successful issue.

THE HUNTERIAN MUSEUM.

In 1799, six years after Hunter's death, Parliament purchased his collection and subsequently handed it over in trust to the Royal College of Surgeons of England for the public advantage. Further grants of money were voted to the College to erect a proper building for preserving and extending "Master" Hunter's collection and to build a theatre for the delivery of public lectures on anatomy and surgery. The museum has been fitly called Hunter's chiefest monument and is surely sufficient for the fame of any man. He worked for it constantly, sacrificed to it his other occupations, and devoted all his earnings to its development. His aim was no less than to illustrate the whole question of life both in health and in disease. Nature's handiwork in all its manifold perfections is there clearly shown forth by the never-ceasing labour of this great intellect. Any ambiguity that may sometimes mar his written words is not to be found in the careful arrangement of specimens which Hunter has displayed to us. The exposition is one almost too great for the human mind to grasp, much more for one man in any adequate sense to realise. Yet Hunter did in the main compass his splendid aspirations. He laid all his friends under contribution. Sir Joseph Banks procured for him every strange creature he could lay hands upon and divided with him the collection he had made during his travels round the world—indeed, for long Hunter had the refusal of every curious animal imported into the country. Smollett, a great friend of Hunter, illustrates the public view when he writes to him, "I mean to send you my poor carcass in a box to be placed amongst your rarities." Hunter's letters to his friends are full of urgent appeals to send him everything which he could utilise for his purposes. His later letters are, if possible, more importunate than the earlier ones. He expresses regret to a correspondent at the loss on the way home of two Havannah birds and a collection of insects. He much wishes for information on the natural history of the swallow whose habits he remembered in Portugal. He wants ostrich eggs just about to hatch and directs them to be put into proof spirit after cracking the shell. "If a foal camel was put in a tub of spirits and sent I should be glad. Is it possible to get a young tame lion or, indeed, any other beast or bird? If chameleons were sent it should be in the spring. I want everything respecting the bee tribe, such as wasps with their nests, also hornets with theirs." What a number of demands and in one letter out of many similar ones, and what an illustration of his zeal in the acquisition of knowledge!

The Hunterian collection of comparative anatomy cannot fail to excite surprise and admiration. We find in it an attempt to unravel the mystery of life, to display the various structures by which the physiological processes in plants and animals are carried on, commencing with the lowest forms and ending with man himself. The anatomical preparations are arranged according to the subjects they are designed to illustrate, and we have besides preparations of healthy and diseased conditions in plants, a series of skulls, skeletons of almost every known form of animal, many examples of deviations from normal types (which Hunter showed to be nothing essentially apart from natural development, but aberrations due to excess or defect or by reason of arrest in the ordinary process of growth), and also a considerable number of fossils. Hunter's collection numbered nearly 14,000 specimens with 10 volumes of manuscript description and notes, beside other catalogues and numerous drawings. He dissected more than 500 different species of animals, many of them more than once, and has left records of 315 dissections. What man ever accomplished such a prodigy of work or ever before illustrated his inquiries on so gigantic a scale? He proves that during the development of the higher organisms the parts usually undergo progressive changes from simple to more complicated structure and that the transitional form can often be recognised as a permanent condition met with in some so-called inferior form of life. The wide-reaching effect of these principles of Hunter finds its further development in the works of Darwin and other philosophers who have followed in his footsteps but have not departed from his methods. Since Hunter's time the number of preparations has increased to almost 50,000 specimens. His threescore of skulls have now grown to nearly 4000, illustrating many difficult problems in ethnology. The pathological collection is five times as numerous and in all the departments there has been continuous increase. Hunter's legacy to the world of wisdom and knowledge was great but the example furnished to us by his indomitable energy and clear recognition of the importance of an extensive knowledge of nature in order to rightly interpret its problems is even of greater value. The College has proved the wise custodian of this great institution and many of its most illustrious sons have devotedly worked towards its completion and perfection. Nowhere in the world exists its like. It is one of our national glories and it is a glory for our profession.[5]

CONCLUSION.

Hunter was a profound philosopher, a great naturalist (using the term in its widest sense), a pre-eminent collector, and the foremost surgeon of his time. It was to make surgery more perfect that all his work subserved and in it he reached the highest rank. He rendered to his art and science greater service than any man had done before him, and his claim to our admiration rests not merely on what he did but on what he suggested might be done. On the brass sacred to his memory in Westminster Abbey this College calls him the founder of scientific surgery. His claim to this proud title was asserted in the first of the Hunterian Orations; it has been renewed in every successive oration where Hunter's life and labours are reviewed by the most eminent of our profession, and it has never been called in question. One cannot but feel impressed at the multitude of the subjects which engaged Hunter's interest and attention, the greatness of his achievements, and the far-reaching influence of so many of his inquiries. His spirit survives in the energy of others who follow in his footsteps and serves to stimulate every student of natural science. He possessed that high form of intelligence which can convert abstract scientific truth to practical uses; hence it is that, finding surgery scarcely more than a mechanical art, he transformed it into a scientific calling, based upon principles which rest on the solid foundations of biological knowledge and collateral science. His supreme endeavour was to study life in all its many-sided manifestations. This is the noblest form of study and the most inexhaustible, yet the problem of life will remain a mystery transcending the power of human investigation or human imagination. Billroth regarded Hunter as one of the greatest men the English nation has produced and that his work on "Inflammation and Gunshot Wounds" is the corner-stone of modern English and German surgery. "From Hunter's time to the present day," he says, "English surgery has had about it something noble and nowhere either in ancient or modern times can the pattern be found of a grander scientific career." Masters of our craft at epochs in surgical history have from time to time declared their art to be then so near perfection that further improvement was impossible. May we not, nevertheless, hope and expect that surgery will accomplish new triumphs and yet greater completeness! I am not of those who think there can be any finality in human progress; to believe so would, I consider, render life no longer worth living in its higher sense and greater aspirations. Rather let us consider ourselves as having but just crossed the threshold of the great temple of science, knowing only a small part of that which still remains to be known, and be mindful of Bacon's words: "Let no man upon a weak conceit of sobriety or an ill-applied *moderation* think or maintaine that a man can search *too farre or* be too well studied in the booke of Gods word, or in the booke of Gods workes, but rather let men awake and cheerfully endeavour and pursue an endlesse progresse or proficiency in both."

Much as we have already achieved in every branch both of the science and art of our profession, more especially during the latter half of this century now drawing to a close, our past experience tends to show that in the future likewise great things shall come to pass. In our own lifetime surgery has been wholly changed. The discovery of anæsthesia has lifted a weight of sorrow from the world, and, as Oliver Wendell Holmes, both poet and physician, has expressed it, "the fierce extremity of suffering has been steeped in the waters of forgetfulness and the deepest furrow in the knotted brow of agony has been smoothed for ever."[6] Anæsthesia has, besides, rendered surgical procedures capable of a realisation which not even in dreams could we have previously supposed possible. It has permitted many new departures in surgery, made many operations feasible which had previously been condemned, and has proved a help of extreme value in the diagnosis of disease. Furthermore, one of the scientific descendants of Hunter, deeply imbued with his spirit, transcendently patient and painstaking in detail as was his master, as minute an observer of nature's ways, and as careful an experimenter, after much trying and much thinking has realised in the discovery of the methods of antiseptic surgery a benefit to mankind which only surgeons can to the full appreciate. What was hazardous before is now rendered safe, what was accomplished with pain and suffering is now free from both. There is scarcely a limit to what might be said in praise of this great work. The name of Lister, like that of John Hunter, will stand forth in the records of scientific progress as one who has immeasurably benefited humanity and as the author of the means whereby surgery has been mainly enabled to make that marvellous progress of which we are all so proud. This is recognized throughout the world, and were I not convinced that our science has fresh achievements in store I should say that Lister had finally crowned the edifice whose corner-stone Hunter laid.

Your Royal Highness, my Lords and Gentlemen,—John Hunter's career has been presented to audiences in this theatre from almost every aspect and his life and work have been reviewed by the greatest of his successors, some of whom have compelled our admiration by the eloquence and the beauty of the language in which they have expressed their thoughts. I do not expect to equal these, yet I would hope that my story, although a "twice-told tale," has aroused in you some measure of sympathetic response. The study of Hunter's works is in itself a liberal education and all who love their profession and who have its well-being at heart will do well to study them. They show his almost superhuman energy, the versatility of his genius, his extraordinary powers of observation, and, beyond all these, the absolute mastery of his will over bodily suffering. Of all the great minds which have illuminated the scientific world and guided its destinies John Hunter's is the one which first directed surgery into the pathways of science and dying left to surgeons a future in the memory of his past. He is the man without whose aid it is impossible to imagine surgery all that it now is; we cannot take his influence away and yet retain all that we now possess. Our science might have spared some other workers but it could not have become the science we know without John Hunter. This great surgeon, one of the greatest men who ever practised surgery, has now long gone to his rest. Cut off in the midst of his glory he died in harness. Yet though he be gone we may well apply to John Hunter what has been said of a pre-eminent statesman lately passed away: "The nation lives that has produced him, may yet produce others like him, and in the meantime it is rich in his memory, rich in his life, and rich above all in his animating and inspiring example."

OBITUARY NOTICES.

According to the terms of the deed already mentioned which establishes the Hunterian Oration it is part of my

---

[5] From Mr. Stewart, the Conservator, I learn that the number of Hunterian specimens now in the museum is 11,324 and the additions since made amount to 37,802 or 49,126 in all. The numbers in the different groups are:—

	Hunterian.	Additional.	Total.
Physiology: plants and animals, arranged according to function	3,751	3,206	6,957
Human osteology: skulls, skeletons	106	6,522	6,633
Comparative osteology	3,802	13,560	17,362
Plants: invertebrata, external forms	1,129	2,468	3,597
Pathology, human and comparative	2,022	8,227	10,249
Calculi	441	2,575	3,015
Instruments	3	916	919
Human normal anatomy	—	308	308
Totals	11,324	37,802	49,126

There were but two Hunterian articulated skeletons, 44 skulls, and six skeletons of fœtus. To these have been added by the College 57 articulated skeletons and 3770 skulls. There is proof that Hunter dissected at least 500 different species of animals, not including repeated dissections of different varieties of the same animal and numerous dissections of plants. He made preparations so as to display the distinctive character of each animal and had careful drawings made from recent dissections besides. He left at his death an enormous mass of manuscript notes, including nine folio volumes of descriptions of dissections of animals, one volume of the natural history of vegetables, notes upon fossils, the notes he compiled for his Croonian Lectures, besides a very large number of observations concerning anatomy and physiology, the experiments he had made, on surgery generally, and also many notes of surgical cases. These were destroyed by Sir Everard Home—a very *holocaust.*

[6] "In this very hour, while I am speaking, how many human creatures are cheated of pangs which seemed inevitable as the common doom of mortality and lulled by the strange magic of the enchanted goblet, held for a moment to their lips, into a repose which has something of ecstasy in its dreaming slumbers? The knife is searching for disease, the pulleys are dragging back dislocated limbs, nature herself is working out the primal curse which doomed the tenderest of her creatures to the sharpest of trials, but the fierce extremity of suffering has been steeped in the waters of forgetfulness and the deepest furrow in the knotted brow of agony has been smoothed for ever."—Introductory Lecture, by Oliver Wendell Holmes, delivered in the Massachusetts Medical College, Nov. 3rd, 1847.

duty to add some appreciative words in memory of those colleagues whose labours have contributed to the improvement or extension of chirurgical science and who have died since my predecessor spoke in this place.

Oliver Pemberton.—The first of these is Mr. Oliver Pemberton, surgeon to the Queen's Hospital in Birmingham, Bradshaw Lecturer in 1894, and member of the Council, who died on March 7th, 1897, at the age of 71 years. His strongly-marked individuality and wise judgments, given always in a kindly and considerate manner, have been much missed. He was educated at King Edward's School in Birmingham. Subsequently he entered St. Bartholomew's Hospital and formed fast friendships with many of the distinguished men belonging to that great institution. It was altogether delightful to listen to the affectionate banter which passed between him and his intimate friend and fellow student Sir William Savory. Pemberton made valuable contributions to surgical literature, was a man of culture, an able clinical teacher, possessed of clear common sense, an acute judgment, and admirable temper. He spoke ill of no man and certainly none could speak ill of him.

James Blake Bailey.—Much too early and to the great loss of this College Mr. Bailey, its librarian, died on April 14th, 1897, at the age of 46 years. Although not a medical man he possessed an intimate acquaintance with medical literature, both English and foreign, and a wise, critical, and literary discernment. He had a knowledge of the contents of our great library at his finger-ends and took a keen and active interest in collecting everything bearing on the life and work of Hunter. Everyone who frequents our library must gratefully remember Mr. Bailey's helpfulness, his accuracy, his never-failing genial courtesy, and recall his bright intelligence and manifest sympathy with those who sought his assistance. Mr. Bailey took a real pride in our library which at present contains some 60,000 volumes and is increasing at the rate of about 1000 volumes each year. We owe it to him that the library has become a perfect model of good arrangement; the books can be consulted with facility and the readers have increased enormously. Mr. Bailey received his early training in the Radcliffe Library at Oxford University, and whilst he was with us he had the energy and ability to keep his terms at Oxford and take an Arts degree. He took a great interest in the byways of literature and wrote the "Diary of a Resurrectionist" which gives a graphic account of the scandals prevailing before the passing of the Anatomy Act.

Walter Rivington.—Mr. Rivington died on May 9th, 1897, at the age of 60 years, whilst still a member of the Council. He was surgeon to the London Hospital and a man of considerable literary attainments. He wrote an exhaustive history of the medical profession. He was a brilliant anatomist and a good surgeon and his work was accurate and painstaking, as is especially manifest in two of his surgical essays, "Tumours of the Orbit" and "Rupture of the Urinary Bladder." He entered the Council as a reformer and had a strong wish to make radical changes in the constitution of the College. He stated his views in debate with courage and discretion also and, although few endorsed his opinions, it was apparent that they were the result of conviction and were urged from a sense of public duty.

Edward Lund.—Mr. Lund, who died on Feb. 4th, 1898, was a provincial surgeon of the best type and a man whose presence at our Council meetings was always welcome. He was an examiner for many years and a Hunterian professor. As surgeon to the Manchester Royal Infirmary, in succession to men like Thomas, Turner, and Southam, he worthily maintained the reputation of the medical school. He was largely instrumental in uniting it to Owens College, whence has eventually arisen the Victoria University. Mr. Lund published many contributions on surgical subjects, one especially good on "Internal Urethrotomy." He had great gifts as a teacher, was resourceful and ingenious as a surgeon, and thorough in everything he did.

Henry Lee.—Mr. Lee, once a member of the Council, Hunterian lecturer and surgeon to St. George's Hospital, died on June 11th, 1898, at the advanced age of 81 years. He early devoted his attention to pathology, especially to that of the veins. Afterwards he attached himself to the study of syphilis, and did much for its better treatment, and in this branch of knowledge he was an unquestioned authority. He was a good practical surgeon, an able clinical teacher, and most genial in his intercourse with men.

SEVEN CASES OF VOLVULUS TREATED BY ABDOMINAL SECTION; THREE RECOVERIES.[1]

BY H. LITTLEWOOD, F.R.C.S. ENG.,
SURGEON TO THE GENERAL INFIRMARY, LEEDS.

DURING the past three years I have had what I believe to be a somewhat unique experience in cases of volvulus, having been called to operate seven times for this condition and having had the good fortune to record three recoveries. Up to the time of seeing my first case (on Dec. 3rd, 1895) I had never seen a case of volvulus either in my own or in the practice of any other surgeon, and the condition is apparently so rare that Kocher stated in a paper on Intestinal Obstruction which he read at the meeting of the British Medical Association at Edinburgh that he had only operated six times for volvulus and that only one of his patients recovered. I have therefore thought that my cases might interest the members of this society and have ventured to bring them before you to-night. I have not arranged them in chronological order but have taken the cases of volvulus of the large intestine (four in number) first and then described the three cases of volvulus of the small intestine. I have described Case 5 somewhat more fully in detail than the others.

CASE 1. *Volvulus of the large intestine (part of the transverse and descending colons and part of the sigmoid flexure); abdominal section; death.*—The patient, a man aged 62 years, was admitted to the Leeds Infirmary under the care of Dr. Barrs on Dec. 3rd, 1895. On Nov. 29th, 1895, he had complained of some pain in his body and from this date neither motion nor flatus had been passed. On the 30th the abdomen had become distended; the distension rapidly increasing. On Dec. 2nd he was crying out with abdominal pain which was relieved by morphia. On admission the abdomen was found to be distended, the distension being very much more marked in the upper part above the level of the umbilicus. He complained of great pain and tenderness which were most intense in this region. No liver dulness could be defined and the heart was displaced upwards so that the apex beat was in the third intercostal space. The abdomen was everywhere resonant. There was no visible peristalsis. There was a small ventral hernia in the right iliac region. No hard tumour could be felt either by abdominal or rectal examination. He had not vomited. The temperature was normal; the pulse was rapid. I saw him with Dr. Barrs and operated soon after.

Chloroform was administed at 12.45 A.M. on Dec. 4th. An incision about three inches long was made in the middle line of the abdomen. The lower limit was at the umbilicus; this was afterwards prolonged to the ensiform cartilage. On opening the peritoneum general peritonitis was found and a considerable quantity of brownish fluid escaped. Part of the colon was enormously distended; it occupied the greater part of the epigastric, umbilical, and right and left hypochondriac regions and pushed upwards the diaphragm. The small intestine, the cæcum, and the ascending colon were not distended. A piece of small intestine was in the sac of the ventral hernia; it was found to be slightly adherent and was removed from the sac. The distended bowel was now brought outside the peritoneal cavity and was found to be a volvulus composed of part of the transverse colon, the splenic flexure, the descending colon, and part of the sigmoid. The volvulus was about 10 inches in diameter at its widest part; it was twisted from left to right, there being rather more than a complete turn; its mesenteric stalk was about two inches in diameter and was situated about the inner part of the left lumbar region. The bowel was of a purple colour and numerous hæmorrhages were present. The volvulus was untwisted but it did not decrease much in size, so it was punctured with a scalpel; a large quantity of foul-smelling gas escaped and a small quantity of liquid fæces. The puncture was closed by a catgut stitch and the gut was easily returned into the abdominal cavity. The patient was in a very collapsed and critical condition after the operation and he died in about 30 hours. During this time he suffered greatly from abdominal pain which was with difficulty controlled by morphia. The bowels were twice opened, the motions being dark brown and liquid.

---

[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society on *Dec. 2nd, 1898.*

The following were the measurements of the volvulus made at the post-mortem examination: From the cæcum to the commencement of the volvulus, 21 inches; from the anus to the termination of the volvulus, 15¼ inches; the convex side of the volvulus, 27½ inches; the mesenteric attachment of the volvulus, 10½ inches; the length of the meso-colon at its widest part, five inches; and its diameter at the widest part, seven and a quarter inches.

CASE 2. *Volvulus of the cæcum, part of the ascending colon, and part of the ileum; operation; recovery.*—A man, aged 61 years, who was sent by the late Dr. Horsfall of Masham, was admitted into the Leeds Infirmary under my care on Nov. 23rd, 1896. The patient had been quite well until a week before admission. He then had pain in the abdomen which had been constant since, becoming at intervals much worse. The bowels had been opened on Nov. 18th, but since that time neither flatus nor motion had been passed. He had suffered from hiccough on Nov. 21 and 22nd, but he had not vomited. He had a right inguinal hernia when he was a young man. In 1870 an operation was performed, but the rupture returned a few years later and since then he had worn a truss. The right inguinal hernia rapidly filled after reduction with what appeared to be collapsed small intestine. On admission the patient's pulse was 90 and of good quality, the tongue was dry, and the lower part of the abdomen was greatly distended and everywhere resonant. The skin near the lower part of the abdomen was tense and distended portions of intestine could be seen and felt. There was no visible peristalsis. On rectal examination the pelvis was found to be filled with distended bowel.

Ether was administered and the abdomen was opened in the middle line below the umbilicus. Distended coils of intestine immediately presented. The incision was prolonged upwards for two inches. The distended portion of the bowel was drawn out of the peritoneal cavity and was found to be a volvulus of the cæcum, part of the ascending colon, and the lower part of the ileum. Some fluid escaped from the cavity. The twisted bowel had a long mesentery and was rotated nearly one and a half times on its mesenteric axis. The various parts were greatly distended, chiefly with gas, and the bowel wall was in a condition of passive congestion. The large intestine was more than five inches in diameter and the small intestine was proportionately distended. The cæcum formed the apex of the volvulus. At the point of twisting were several small hæmorrhages into the mesentery. The twisting of the bowel was from right to left and it was untwisted in the opposite direction and the contents of the volvulus were gradually forced onwards by gentle manipulation. The anus at the same time was dilated and a great quantity of flatus and liquid fæces were passed. The hernia was reduced and the contents were found to be normal. The bowels were then returned into the peritoneal cavity. At this stage the patient stopped breathing and artificial respiration was performed for four minutes. The abdomen was closed and a small portion of the cæcum was stitched to the lower part of the wound, so that if the obstruction continued a tube might be inserted and also to fix the bowel to prevent a recurrence of the twisting.

On Nov. 24th the patient said he felt stiff inside. The temperature was normal and the pulse 96. Rectal injections of four ounces of warm water every four hours were employed. The temperature was 99·4° F. on the day of the operation; after that it was normal. The patient made a good recovery; he got up at the end of three weeks and went home on the twenty-fifth day after the operation.

CASE 3. *Volvulus of the sigmoid flexure; operation; death.*—The patient was a woman, aged 57 years, who was under the care of Mr. West of Morley. I saw her with him on March 25th, 1896, and I operated at 3 P.M. on the same day. The history of the case showed that she had had an attack of intestinal obstruction which commenced on Jan. 18th, 1896. On Feb. 6th the bowels were suddenly relieved. The patient said that she had never been quite well since. On March 19th she commenced to suffer from pain in the body and vomiting. The bowels were opened on March 22nd and some flatus had passed, but since then nothing had passed. She was a very thin woman. The abdomen was distended, especially in the hypogastric and left iliac regions. There was some visible peristalsis. The abdomen was everywhere resonant and no tumour could be felt. On rectal examination no narrowing in the rectum was discovered. Douglas's pouch was filled with greatly distended bowel.

Chloroform was administered at the operation. The abdomen was opened in the middle line below the umbilicus by a three-inch incision. The hand was inserted into the peritoneal cavity; most of the small intestines were collapsed. The pelvis and the lower part of the abdomen were filled with a hugely distended coil which turned out to be a volvulus of the sigmoid flexure; it was about four inches in diameter. This was pulled outside the abdomen and was found to be twisted on its mesenteric axis from right to left. About 18 inches of the sigmoid formed the volvulus. This was untwisted; there was also a narrow band from the omentum crossing it, the other end of which was attached to the right iliac fossa; this was divided. As the volvulus contained a large quantity of liquid motion and gas and the walls appeared considerably damaged by the distension an incision was made in its long axis about an inch in length and about a quart of thin fæcal material and a large quantity of foul-smelling gas were evacuated. This was closed by a continuous Lembert's suture, the bowel was returned into the abdomen, and the abdominal wound was closed. The patient stood the operation well; the pulse was about 100 at its completion. The morning after the operation the temperature was 103°F., and the pulse was 104. No flatus was passed after the operation nor did she vomit. She got gradually worse and died 40 hours after the operation. There was no post-mortem examination.

CASE 4. *Volvulus of the sigmoid flexure; operation; recovery.*—The patient was a healthy, well-nourished girl, aged 10 years, who was under the care of Mr. Arthur Ellison of Leeds. I saw her with him on Jan. 25th, 1898, and operated at 10.30 P.M. The patient had commenced to feel ill on Jan. 24th and on the next day she complained of of pain in the body, which soon became distended and was associated with a rapid pulse and vomiting. When I saw her she was greatly collapsed, the pulse was rapid, and the hands were becoming cold. The abdomen was much distended and was tender and not moving with respiration. No localised swelling or enlargement could be seen or felt. On rectal examination the pelvis appeared to be full of distended intestines.

Chloroform was given by Mr. Ash and Mr. Ellison assisted me in the performance of the operation. The abdomen was opened in the middle line below the umbilicus by an incision three inches in length. Some thin semi-purulent fluid escaped and some distended and inflamed coils of intestine presented. Some of these were pulled outside the abdomen and protected by hot towels; between these coils were several pieces of yellowish-white lymph. There appeared to be a general peritonitis. A large distended coil was now felt which filled up the pelvis and turned out to be a volvulus of the sigmoid flexure, about 12 inches in length and about three inches in diameter. It was twisted on its mesentery from left to right; the lowest portion of the volvulus appeared to correspond to the top of the rectum. The volvulus was untwisted without pulling it outside the abdomen. When this had been done Mr. Ellison thoroughly dilated the sphincter ani and this enabled me to squeeze out a large quantity of flatus and fluid fæces from the sigmoid and from the distended coils of bowel beyond the volvulus, so that I could now easily replace the small intestines. At this stage the patient became much worse; the pulse could scarcely be felt. Brandy was given hypodermically and the abdomen was closed as rapidly as possible as I thought that the patient would not live long enough for me to complete the operation. The operation having been completed hypodermic injections of brandy and strychnia were given. After two or three hours she greatly improved and she swallowed a little brandy by the mouth. As she complained of great pain one-sixth of a grain of morphia was given hypodermically. Six hours after the operation she passed flatus and some urine. The temperature was 101·6°F. and the pulse was 152. On Jan. 27th the pulse was 120 and the temperature was 98·6°. After this the temperature was normal until Feb. 12th, when it suddenly went up to 103°; this was associated with some shivering and pain in the body which only lasted a few hours. After this the temperature was normal. The pulse gradually diminished in frequency. The bowels were at first well opened by means of saline purgatives and enemata. The patient got up on Feb. 27th and subsequently she made [illegible]

CASE 5. *Volvulus of* [illegible] *…tion; gangrene of volvulus;* re[illegible] *…ent* *suture of the bowel; recovery.*—The patient, a woman, aged 32 years, was under the care of Mr. Woods and Mr. Keighley of Batley. I saw her with them on June 9th, 1897, at 1 A.M., and operated soon after. The patient had been confined three weeks ago and was doing well; she had got up on the tenth day for a short time. On June 3rd, in the middle of the day, she had been suddenly seized with intense pain in the body and signs of intestinal obstruction developed later. On the 4th she had been seen by a consulting surgeon who ordered her small doses of belladonna and enemata. He saw her the next day and found her condition much improved; the bowels had been opened three or four times and the body was less distended. A few hours later she had become much worse, vomiting being incessant, and the distension of the abdomen becoming more marked. The symptoms of intestinal obstruction had increased in severity until I saw her. She was then very ill; the pulse was 150 and feeble, and the hands were getting cold but not moist. She was vomiting frequently; the vomit was very foul-smelling. The tongue was furred and moist. The abdomen was greatly distended and not moving with respiration. Coils of intestine could be seen and felt to move. She complained of great pain and there was a good deal of tenderness over the lower part of the abdomen.

At 1.30 A.M. I proceeded to operate. Ether was given by Mr. Woods and Mr. Keighley assisted. An incision about four inches in length was made in the middle line below the umbilicus. There was a good deal of bleeding from the abdominal wall. On opening the peritoneal cavity three or four ounces of foul-smelling red-coloured fluid escaped. On introducing the hand coils of small intestine were found matted together in the umbilical and hypogastric regions and in the pelvis. Some of the coils were adherent to the pelvic organs. The uterus was large. On looking into the peritoneal cavity some coils of intestine were noticed to be of a dark purple colour; these were pulled outside and were found to be a volvulus of the small intestine about 14 inches long. This portion of the bowel was distended but had not altogether lost its polish; it was almost everywhere adherent by soft adhesions to the surrounding small intestines which were also distended. The volvulus was untwisted and separated from the small intestines to which it was attached; gas passed freely out of the volvulus. The bowel was twisted rather more than a complete turn from right to left on its mesenteric axis and was hanging downwards; it was deeply grooved at the point of constriction. At this stage artificial respiration had to be resorted to and hypodermic injections of ether and brandy had to be administered; after some minutes the patient again breathed. The operation was rapidly concluded, more blood-stained offensive fluid was removed from the pelvis, and a Bantock's tube was inserted. The wound was closed except about an inch of the lowest part; the volvulus was placed as near this opening as possible. The operation lasted about 30 minutes. After the operation the patient soon became conscious and she vomited twice.

On June 9th, at 4 P.M., the bowels acted. The motion was very offensive. The patient felt sick, but she did not vomit. Abdominal distension was very marked. The pulse was 140 and the temperature was 104° F. The patient was in a very critical condition after the operation. On the 11th the temperature was 100° and the pulse was 104. The bowels were opened after a simple enema. Feeding was conducted entirely by nutrient enemata. The bladder was emptied by catheter. The wound was dressed and iodoform which had been used was discontinued, as the patient had some eczema of the body, arms, and legs, probably due to the drug. This completely cleared up in about 10 days. The Bantock's tube which had been emptied at frequent intervals was now removed as the discharge had greatly diminished in quantity. The patient now complained of great pain and swelling of the right leg and it was found that she had thrombosis of the femoral vein. On the 12th, at 8 A.M., the abdominal distension was quite gone. The patient was passing flatus freely. There was more pain in the leg and it was much more swollen. At 8 P.M. the patient was very restless and she complained of pain in the abdomen; an offensive discharge had come through the dressing. A simple enema was given with a good result. After this the patient slept for an hour and then woke up feeling hot and restless. The pulse was 140, the temperature was 102·4°, and the respiration was 36. The wound was dressed at midnight; the discharge was fæcal and large in quantity. Some portion of the volvulus had evidently given way. The wound was dressed every two hours. On the 13th the patient was much better and she passed urine naturally. On the 14th feeding by the mouth was commenced and the rectal feeding was gradually diminished. The bowels were opened daily by simple enemata. On the 22nd an offensive slough was noticed to protrude from the lower part of the wound. On the 24th I pulled on this and removed a slough about a foot long which consisted of small intestine greatly decomposed, evidently the whole of the volvulus. The patient was now entirely fed by the mouth. The pain and swelling in the leg were much less. On July 4th the patient got up for an hour. After this she continued to recover, getting up every day. On August 7th she was admitted to a surgical home in Leeds to have an operation performed for the restoration of the continuity of the bowel. During the past three weeks she had been getting up and going out every day. Most of the motion was discharged through the fistulous opening; two or three times some motions had been passed per rectum. The patient had had three attacks of obstruction, as the fistulous opening became almost closed; these attacks had been associated with great pain and vomiting. On dilating the fistulous tract relief had soon been obtained with copious discharge of motion. After admission to the "Home" she was very well until early in the morning of August 9th. I was called to see her at 5 A.M. She was then suffering from great pain in the body and was very collapsed. The abdomen was distended and the temperature was 101·6°. During the preceding 24 hours very little had been discharged through the fistulous opening. After some difficulty a No. 12 rubber catheter was passed into the bowel through the sinus and after that some fluid contents escaped. The sinus was an inch in length before it opened into the bowel and it appeared that this opening had practically closed. One-sixth of a grain of morphia was given hypodermically. After this the patient was greatly relieved and had the bowels well moved through the fistula.

On August 11th, at 9.15 A.M., the operation was commenced. The pulse just before operation was 120, and the temperature was 100·4°. Ether was given by Mr. Dixon. I was assisted by Mr. Walter Thompson and Mr. F. Talbot. An incision about three inches long was made in the middle line above the old scar, and the abdomen was opened. This exposed the omentum which was adherent to the viscera about the old incision. The finger was then passed inside the abdomen to the left of the sinus and it was found that the adhesions only extended for a short distance from the middle line. The area of adhesion around the sinus to the abdominal wall appeared to be a circle about two inches in diameter. The incision was now continued downwards on either side of the external orifice of the sinus so that this was isolated from the abdominal wall, and the incision was continued through the abdominal wall in the middle line for three inches below this. The portion of omentum attached to the viscera near the *cicatrix* was transfixed in six places and ligatured with fine silk and divided. This enabled me to make a complete examination of the parts. It was now found that several coils of intestine were adherent together and one coil was adherent to the top of the uterus. These adhesions were separated by means of a blunt dissector and the finger; one or two vessels were ligatured. Free access to the parts was thus obtained. About six inches above the fistulous opening and the same distance below the bowel was surrounded by means of a piece of indiarubber tubing. The fistulous track and the portion of skin surrounding the orifice, which had previously been separated were now carefully dissected out and removed. At one end of the fistula a small opening into the upper part of the bowel was found. This portion of bowel was greatly distended and there was some active peritonitis and actually some yellow flakes of lymph between some of the coils; at the other end of the fistula a small opening was found communicating with the lower portion of the bowel. The edges of the bowel were now pared. The portion of bowel below the fistula was much contracted. To make the openings of equal size the lower one was enlarged by dividing all the coats for a short distance at a point of the opening directly opposite the mesenteric attachment. The edges of the bowel were now stitched together by means of two continuous fine silk sutures, each going half-way round the circumference, beginning and terminating by a knot, all the coats of the bowel with the exception of the mucosa being included in the suture. Two or three sutures now close the gap in the mesentery. The sponges were removed and the omentum was brought down to cover the parts. The abdominal wound was closed. The operation lasted one hour and a half. The patient was very collapsed at the end; the pulse was 180. An injection of strychnia and brandy was given as well as an enema of brandy and water. The patient made a good recovery. She was fed by nutrient enemata for five days and after that by the mouth. The bladder was emptied by catheter for five or six days. The bowels were opened by a simple enema on the 21st and after that every day by means of enemata. A small stitch abscess formed which was opened on the 19th. The patient got up at the end of three weeks and made very rapid progress. The temperature, which was 100° at the time of the operation, varied between 100° and 101° for two or three days; after that it was normal, with the exception of a rise on the 26th and 27th, when it reached 102°. I received the following letter from Mr. Woods a few days ago: "Mrs. —— was prematurely confined at the end of seventh month of twin boys on July 22nd, 1898. The elder died on July 31st, the younger on August 2nd. At the present time the patient expresses herself as being in perfect health and quite able to do her household duties. She feels as well as ever she did."

CASE 6. *Volvulus of small intestine; operation; death.*—The patient, a man, aged 53 years, was under the care of Mr. Griesbach of Garforth. I saw him at 8 P.M. on May 4th, 1898, and operated on May 5th at 9.30 A.M. The patient had been first seen by Mr. Griesbach on April 29th. He had then complained of vomiting and pain in the body and there was some distension. On the next day the bowels had been opened, but no flatus passed. After the first day there had been no vomiting. The body had become more distended and tender. The temperature did not rise above the normal. The pulse had gradually increased in frequency and when I saw him it was 130. His hands and face were then pinched but not cold. The abdomen was distended and everywhere resonant; the distension was most marked on the left side No tumour could be felt. Distended coils of intestine could be seen but there was no peristalsis visible. Nutrient enemata with strychnia were given during the night and on the next morning the condition of the patient was about the same.

Mr. Griesbach administered ether and my house-surgeon, Mr. F. Talbot, assisted me. The abdomen was opened through the left linea semilunaris; some blood-stained fluid escaped. Some greatly distended small intestines presented which were of a purplish colour; several of these coils were pulled outside and were surrounded by hot towels. It was now found to be a volvulus involving several feet of small intestine twisted from left to right on its mesenteric axis. This was untwisted. It appeared to have made rather more than one complete turn and at the point of twisting there was a deep ulcer in the mesentery around which were some flakes of purulent lymph. The mesentery was torn near the ulcer in untwisting it, this caused some delay in stitching up as a vein was perforated and only with difficulty was it secured. As the bowel appeared paralysed and the distension was not much diminished an incision was made into it and a Paul's tube was inserted; from this a large quantity of foul-smelling contents escaped. The volvulus could now be easily reduced. The abdominal wound was closed, fixing into it the portion of intestine into which the tube had been inserted. The operation lasted about an hour and the patient stood it well He died on May 10th. For the first two or three days after the operation his condition had improved and he had appeared to be more comfortable; the pulse had improved in quality and had become less frequent. He had passed large quantities of flatus and the bowels had been well opened two or three times. At first large quantities of thin fæcal material had come through the tube, but afterwards it was thin, bile-stained fluid, from 10 to 12 ounces coming during the day. During the last 48 hours of life he had rapidly got worse, his hands becoming cold and blue, and there had been a good deal of twitching. The urine had been scanty and painful to pass. There was no post-mortem examination.

CASE 7. *Volvulus of the small intestine; tuberculous mesenteric glands and adhesions, operation; death.*—A man, aged 20 years, was admitted into the Leeds Infirmary under my care on March 15th, 1898 On March 13th at 3 A.M. he had been suddenly awakened by an acute pain in the abdomen, most marked about the umbilicus. Since then the pain had been more or less constant with paroxysmal exacerbations. The pain was less severe after passing flatus. He had commenced to vomit at about 7 A.M. The vomiting had been frequent, latterly becoming offensive. The bowels had not been opened since March 11th. Three or four enemata had been given. On admission the abdomen was found to be slightly distended, especially in the umbilical region. The abdominal walls were rigid and not moving with respiration. No tumour could be felt. There was no visible peristalsis. A doughy sensation in the pelvis was revealed on rectal examination.

The operation was carried out on March 16th at 10 A.M. Ether was administered. The abdomen was opened in the middle line by an incision three inches long below the umbilicus. There was some peritonitis. On introducing the hand into the peritoneal cavity the pelvis was found to be filled with collapsed small intestine. Above this were greatly distended bowels which were of a purplish colour. These were pulled outside the abdomen and protected with hot towels. They were found to be a volvulus, involving about two or three feet of small intestine completely twisted from left to right on its mesenteric axis. The mesentery forming the stalk of the volvulus was puckered and in it was found some enlarged and caseous glands; about two inches of small intestine were adherent to this. The volvulus was untwisted and then the adherent bowel was separated from the mesentery. In doing this a small tear was made into the bowel which was stitched up. The volvulus could be partly emptied, gas and liquid motion passing into the lower portion of the intestine. The abdominal wound was closed and a portion of the volvulus was secured to the lower end of the wound, so that it could if necessary be easily opened.

On March 17th, at 10 A.M., the patient was restless. There had been no vomiting since the operation. The pulse was 126 and the temperature was 99·6° F. At 3 P.M. the patient was delirious. There was no action of the bowels nor was any flatus passed. The face was flushed and dusky. At 6 P.M. the portion of bowel stretched to the lower part of the wound was opened and a small Paul's tube was inserted. At 11 P.M. the pulse was 136, the face was livid, and the patient was now quite maniacal and very restless. One-sixth of a grain of morphia was given hypodermically. There had been no flow of intestinal contents through the Paul's tube and no passage of flatus or motion per rectum. The patient had not vomited since the operation. He died at 4 A.M. on the 18th.

A post-mortem examination was made by Dr. T. Wardrop Griffith. On opening the abdominal cavity the small intestine was found to be immensely distended for rather more than half its course. The lower few feet of this formed a partially untwisted volvulus and presented dark semi-gangrenous patches; the artificial anus was made into the lower part of this portion of gut. The remaining small intestine, about four feet, was attached by puckered mesentery. The puckering was more marked at the upper portion of this part of the gut. Here the glands of the mesentery were indurated, being in part caseous and in part calcareous. A fold of sigmoid flexure was involved in these adhesions; other portions of the large gut were normal and contained large scybalous masses. The other organs were normal.

What strikes me most forcibly in seeing cases of intestinal obstruction is the difficulty in making a diagnosis and it is probably this very difficulty which fascinates one. I have to confess that out of the seven cases I only made a correct diagnosis in one; that was Case 2, and I made that with some reservation, as although the chief signs were present still the patient did not appear ill enough to warrant the diagnosis of such a grave condition. Case 1 we thought probably might be a case of perforated gastric ulcer. In the other cases there was so much general peritonitis and distension that I think the making of a correct diagnosis as to the actual cause of obstruction was well-nigh impossible. Volvulus of the small intestine is considered a very rare condition unless some cases of transient acute obstruction which readily clear up are really cases of partial volvulus. Descriptions of actual cases demonstrated either on the operating table or in the post-mortem room are certainly very rare. Mr. Thorburn has a very valuable paper on this subject in the *Manchester Medical Chronicle* for June, 1898, with a record of three cases, one of which is an undoubted case of volvulus, and I agree with him in thinking that a volvulus is the best explanati of the other cases. Case 5 suggests that the disarrang on the emptying of the gravid uterus may be the starting of a volvulus of the small intestine. The sudden onset in this case may have been caused by the patient assuming the upright position. I have thought that if the symptoms in this case had commenced a few days after the confinement a diagnosis of post-puerperal septic peritonitis might have been made, and if this is a reasonable suggestion it is possible that there are cases which are diagnosed and certified as post-puerperal peritonitis which are really cases of twisting of the bowels and that the peritoneum is infected from the intestine and not from the uterus. It is also more than probable that the correct explanation of some of the fatal cases of peritonitis occurring after ovariotomy and other similar operations may be that the infecting organism comes from a twisted or kinked bowel. Dr. Donald's case quoted by Mr. Thorburn supports this view—a case in which there was found, sharply defined, gangrene of five feet of ileum 35 hours after a simple ovariotomy—and I imagine that most operators must have seen cases of peritonitis after ovariotomy in which they have suspected that the infection has been derived from the intestinal tract. As to the causation of volvulus, in the large intestine a long mesentery appears necessary for its production. The normal length of the mesentery of the small intestine would seem to be favourable for the production of a volvulus, the small intestine being as it were suspended by its mesentery. In none of the cases did previous constipation apparently play any causative part—in fact, it was quite curious to note that in the cases of volvulus of the large intestine there were no hardened fæces, the contents being gaseous and liquid. In some of the cases visible peristalsis was noted. I am inclined to think that this movement occurred in the bowel above the twist and not in the volvulus itself. It appears to me that peristalsis is not likely to occur in the twisted gut.

The treatment of the volvulus adopted varied in the different cases. In Case 1 the volvulus was simply reduced after letting out the gas. In Cases 2 and 4 the anus was dilated and the contents of the volvulus and colon were squeezed out without opening the bowel, the after-treatment consisting of the administration of saline purgatives and washing out the bowel. Both these cases recovered. In Case 3 the contents of the volvulus were evacuated after incision. In Case 5 the volvulus was simply untwisted and the pelvis was drained. The volvulus subsequently becoming gangrenous was then removed and later the intestinal continuity was restored. In Cases 6 and 7 the intestine was opened and a Paul's tube was inserted in the coil, in the former case at the time of the operation and in the latter 24 hours after.

The mortality in cases of intestinal obstruction, whether from volvulus or from any other cause, is fortunately diminishing, and this is undoubtedly due to the fact that the profession is appreciating the great importance of early surgical interference in the large majority of cases of that condition.

Leeds.

DIPHTHERIA IN LONDON.—The first four weeks of the present year have witnessed in London a fall alike as to amount and fatality of diphtheria as compared with the four concluding weeks of 1898. In the December period in question there were 1045 notified cases, yielding a weekly average of 261, whilst in the January period only 959 notifications were made and the weekly average fell to 240 cases. In December two sanitary areas and in January one such area remained uninvaded. In December five districts had each upwards of 50 cases, 386 in all, and in January four districts had more than 50 cases each, an aggregate of 289, whilst four other invaded localities had only six cases between them. The registered deaths numbered 176, or 44 per week in the December period and caused a case rate of mortality of 16·8 per cent. In January the total mortality was only 125, or 31 weekly, and the case rate 13·0 per cent. These 125 deaths would have been 169 had the corrected decennial average been maintained for the corresponding weeks of the years 1889–98. In the Outer Circle the registered mortality was also much smaller in January than in December. In the earlier period 84 deaths, or 21 weekly, were recorded, of which 40 belonged to West Ham Registration District; in January only 57 deaths, or 14 weekly, were registered, of which 20 belonged to the West Ham area.

NOTES OF 84 CASES OF SYPHILIS TREATED BY THE INTRAVENOUS INJECTION OF CYANIDE OF MERCURY.

By ARTHUR CHOPPING, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON TO THE LONDON MALE LOCK HOSPITAL.

DURING my term of house surgeon to the London Male Lock Hospital I had the opportunity of watching the effect of the various methods of treating syphilis and came to the conclusion that for hospital practice, for the more serious lesions, and for cases which can be seen daily, the intravenous injection of mercury was far superior to the other methods employed. I thought it might be interesting to give the notes of the cases I treated in this manner. It may be well before proceeding further to explain briefly the method of procedure. It is simple and with ordinary care is unattended with any special risks. The part of the arm where the injection is to be made is rendered aseptic by washing and swabbing over with a solution of carbolic acid. The veins of the forearm or the bend of the elbow are chosen as being the most prominent and easy to get at. A rubber tourniquet is applied to the upper part of the arm to make the veins stand out, and a fine needle of a hypodermic syringe containing 20 minims of a 1 per cent. solution of cyanide of mercury is introduced into the vein chosen, in the direction of the blood-stream. The operator knows when the needle is inside the vein by the sensation which is imparted to the syringe. The tourniquet is then removed, the fluid is injected into the vein, the needle is withdrawn, and an aseptic swab is applied with a small amount of pressure to the puncture for a few minutes. The injection is made every morning unless the patient complains of diarrhœa, which rarely happens, or unless there is some other contraindication. The injection is quite painless unless it has missed the vein when it causes acute pain and swelling. The pain and swelling can usually be reduced in a day or two by means of hot fomentations. Occasionally, however, the swelling persists for two or three weeks as an indurated nodule. In a small percentage of cases bruising of the tissues surrounding the vein occurs, due to slight extravasation of blood around the puncture, and can often be overcome by using a finer needle.

The advantages which are claimed for this line of treatment are—1. As the injection is made daily the patient is under constant observation. 2. The exact quantity of mercury introduced into the system is known. This is not the case when pills or inunctions are used. 3. As the drug is administered by intravenous injection the patient is rapidly brought under its influence (with greater rapidity than when administered by the mouth or skin) a marked advantage in cases where it is necessary to produce the full effect of the drug as speedily as possible, such as iritis, otorrhœa, bad ulcerative laryngitis, &c. 4. The rapidity with which serious lesions and visible evidences of the disease clear up. 5. The treatment by intravenous injection is especially useful in cases which have not responded to the ordinary methods of treatment, such as pills, inunctions, &c. In three cases, Nos. 22, 27, and 69, polyuria occurred for a few days. In two cases, Nos. 24 and 54, diarrhœa occurred, which was, however, easily kept under control by astringents and omitting injections for a few days. In two cases, Nos. 13 and 33, salivation occurred which was controlled by astringent washes and mouth hygiene. In three cases, Nos. 46, 59, and 74, there was a difficulty in making the veins sufficiently prominent. When the large number of cases dealt with is remembered these complications are scarcely worth mentioning, and can scarcely be called disadvantages especially as they were very slight and rapidly disappeared. Nine of the following cases are not classified, as the patients refused to be thus treated or were discharged for improper conduct. Cases of phimosis, where it was necessary to circumcise or to slit up the prepuce, healed rapidly, and in only one case, No. 30, did the wound thus formed indurate. The average stay in the hospital per case was 23·2 days. All the cases, with but one exception, No. 43, showed very marked and rapid improvement. It is not claimed that this method acted quite alone in producing these good results. In the worst cases other adjuvants were used such as cod-liver oil, iron, and a correct diet, and in all

SYNOPSIS OF 84 CASES OF SYPHILIS TREATED BY THE INTRAVENOUS INJECTION OF CYANIDE OF MERCURY.

Primary and Secondary Syphilis.

No.	Age in years	Previous history.	Nature of lesions.	No. of injections.	Time.	Result.	Remarks.
1	20	—	Phimosis for 4 weeks; concealed chancre; fading macular syphilide; inguinal adenitis.	14	14 days.	Improved +	Rash faded; phimosis reduced; sore healed.
2	20	Connexion 3 months ago.	Phimosis for 3 weeks; inguinal adenitis; papular eruption for 1 week.	27	30 days.	Improved. +	Sore healed; rash disappeared.
3	29	Chancre for 11 weeks; had had treatment with mercury (pills) but was getting worse.	Multiple sores at the frenum; chancre; meatus urinarius; adenitis, balanitis, and œdema; papular syphilide for 4 days.	24	28 days.	Improved. +	No symptoms present; sore healed; rash faded.
4	40	Chancre 5 months ago, 3 weeks after connexion; rash 2 weeks later.	Phimosis; concealed sore; adenitis; syphilide on the arms, back, legs, &c.; condylomata ani (circumcision).	16	27 days.	Improved. +	On the twenty-seventh day all symptoms had disappeared. Until the twenty first day veins would not stand out; inunction for 6 days every night.
5	33	Connexion 5 weeks before admission.	Chancre on the penis for 1 month; mass of enlarged glands; squamous syphilide of the face.	14	26 days.	Improved. +	Sore and bubo healed, spots faded, glands much reduced in size; oleate of mercury ointment applied to the glands.
6	21	Connexion 10 weeks before admission	Urethral chancre; swelling and inflammation of the whole penis; profuse papular eruption, adenitis, anæmia, and alopecia.	26	29 days.	Improved. +	All symptoms of syphilis disappeared, sore healed, rash faded, and the penis normal.
	30	Connexion 4 weeks before admission.	Chancre on prepuce for 10 days; papular eruption; inguinal adenitis.	11	17 days.	Improved. +	Sore healed; rash disappeared.
8	30	Connexion 9 weeks ago.	Indurated coronal chancre for 8 weeks; profuse squamous eruption, pustulous in places, for 1 month; throat injected.	30	32 days.	Improved. +	Sore healed; spots nearly gone.
9	27	Connexion 4 weeks ago.	Sore appeared 3 days after connexion, when he applied $CaSO_4$; adenitis, papular syphilide, and alopecia.	13	38 days.	Improved. +	At the sixth injection, the teeth being loose, injections were discontinued for 3 weeks and then resumed; after 13 injections the spots faded; sore nearly healed; hair stopped coming out.
10	29	Coronal chancre for 2 months.	Indurated chancre; profuse papular syphilide 3 weeks; adenitis.	19	21 days.	Improved. +	Sore healed; spots nearly gone; took his own discharge.
11	18	Primary sore on the penis 5 months previously.	Sloughing prepuce for 6 weeks; condylomata scroti and in inguinal region; profuse macular eruption, annular round the mouth and nose.	14	15 days.	Improved. +	At the sixth injection condylomata ani disappeared; after fifteen injections no signs of syphilis were present.
12	21	—	Chancre on the penis for 3 months; profuse macular rash for 2 months; adenitis, double iritis, condylomata.	14	15 days.	Improved. +	At the eighth injection the sores healed; the iritis was cured; at the fourteenth all signs disappeared.
13	33	Intercourse 7 weeks previously.	Sores on the prepuce for 3 weeks; general squamous pustular eruption; adenitis.	18	30 days.	Improved. +	At the fifth injection the gums were badly touched; no injection for 10 days; during this time the rash faded. At the eighteenth injection the sore healed and the rash had faded.
14	18	—	Phimosis; concealed chancre; œdema scroti; marked macular eruption.	17	17 days.	Improved. +	At the twelfth injection the rash faded; at the seventeenth injection the sore healed.
15	27	Small sore 9 days after connexion 6 weeks ago	Indurated sore of the glans; œdema of the penis; very profuse papular eruption.	21	21 days.	Improved +	Sore almost healed; rash nearly gone; no other symptoms.
16	19	Connexion 4 months ago.	Remains of indurated chancre on the penis; ulcerated throat; squamo-papulo-pustular syphilide; adenitis; pains in the limbs.	21	26 days.	Improved. +	Pains have disappeared; rash faded; wards closed.
17	33	—	Indurated chancre on the glans for 6 weeks; adenitis; papular syphilide.	9	17 days	Improved. +	Sore healed; spots fading; wards closed.
18	—	Sore on the penis; sore throat and mouth 1 year ago.	White patch on the tongue; adenitis; inguinal; small sore under the surface of the penis.	4	7 days.	Improved +	Much better; wards closed.
19	22	—	Phimosis; concealed sore; adenitis; condylomata ani, ulcers on the tonsils.	13	15 days.	Improved +	Circumcision; condylomata healed, throat well; circumcision wound healthy.
20	25	Has been treated with mercury; gums touched.	Coronal chancre; adenitis; throat injected.	8	9 days	Improved. +	Sore healed.
21	41	Connexion 2 months previously.	Hard collar of induration around the corona; inguinal and post-mastoid adenitis.	14	17 days.	Improved. +	All the symptoms disappeared.
22	19	Connexion 8 weeks previously.	Phimosis; concealed chancre; adenitis; profuse erythema.	20	20 days.	Improved. +	Complained of polyuria; there was no albumin. The rash had nearly gone; circumcision.

SYNOPSIS OF 84 CASES OF SYPHILIS TREATED BY THE INTRAVENOUS INJECTION OF CYANIDE OF MERCURY—(*Continued*).

Primary and Secondary Syphilis—(Continued).

No.	Age in years.	Previous history.	Nature of lesions.	No. of injections.	Time.	Result.	Remarks.
23	36	Sore on the penis 4 months ago.	Maculo-squamous syphilide; rupia; throat congested.	13	14 days.	Improved. +	Spots fading; throat well; wards to be closed.
24	19		Sloughing of the prepuce; mass of enlarged glands in the groin breaking down; maculo-papular syphilide.	13	17 days.	Improved. +	At the seventh injection diarrhœa occurred and it was omitted for 2 days. Circumcision; groin scraped. At the tenth injection the spots had gone.
25	36	—	Phimosis; chancre on the prepuce; adenitis; profuse papular eruption.	28	30 days.	Improved. +	Circumcision; spots disappearing. Circumcision wound healed.
26	17	—	Phimosis; papular syphilide; adenitis; tonsils ulcerated; circumcision.	32	33 days.	Improved. +	At the tenth injection the rash was fading. Circumcision wound healed. At the thirty-second injection the rash had gone.
27	34	—	Sloughing sore on the glans; adenitis; profuse roseola.	37	40 days.	Improved. +	Rash faded; sore nearly well; complains of polyuria at night; there was no albuminuria in the urine.
28	42	Connexion 6 weeks previously.	Sloughing indurated sore under the surface of the glans and prepuce; adenitis; papulo-macular eruption; throat ulcerated.	10	11 days.	Improved. +	Throat well; sore much better; looks healthy; wards to be closed.
29	29	Connexion 2 weeks previously.	Sloughing sore on the scrotum for 2 months; sore on the penis for 2 weeks; adenitis.	12	17 days.	Improved. +	Sores on the scrotum; penis looked very healthy and nearly healed; wards to be closed.
30	18	—	Inflamed phimosis; circumcision; the scar indurated; roseola; inguinal adenitis.	7	26 days.	Improved. +	The circumcision wound healed; eruption faded; induration subsided.
31	26	Connexion 8 weeks previously.	Indurated chancre 2 weeks; adenitis; profuse macular eruption; throat congested.	9	10 days.	Improved. +	Rash almost disappeared; sore nearly healed; own discharge.
32	31	Connexion 9 weeks previously.	Phimosis; concealed chancre; adenitis; roseola.	8	9 days.	—	Rash gone.
33	23	Had been treated with mercury for 5 weeks.	Phimosis; concealed sore; profuse general papulo-macular syphilide; adenitis; circumcision.	12	20 days.	Improved.	At the twelfth injection the gums touched, inunction for last 3 days; most of rash faded; own discharge.
34	21	Primary sore for 10 weeks.	Phimosis; concealed sores; adenitis; macular eruption; condylomata ani.	8	8 days.	Improved.	Own discharge.
35	30	Chancre for 4 weeks.	Phimosis; ulceration of the prepuce; papular rash; adenitis; slit up.	18	19 days.	Improved. +	Rash faded; sores healed; penis which was very filthy was now normal.
36	24	Last connexion 4 weeks previously.	Phimosis for 3 weeks; indurated chancre on the prepuce; general pustular eruption.	7	14 days.	—	Own discharge.
37	—	Connexion 2 months previously.	Phimosis; circumcision; indurated sores at the frænum; adenitis; roseola.	12	20 days.	Improved. +	Sore healed; rash faded; circumcision wound healed.
38	22	—	Two indurated sores under the surface of the prepuce; profuse eruption on body; buboes in the groin.	26	39 days.	Improved. +	Sores healed, as had also buboes; rash disappeared.
39	21	Last connexion 4 weeks previously.	Indurated chancre; adenitis; erythema; anæmia; sore throat.	13	14 days.	Improved. +	At the fifth injection the rash faded; at the thirteenth *injection* the sore healed. The glands were much smaller.
40	26	Primary sore for 3 months.	Ulceration and condylomata of the left tonsil; papular syphilide.	14	14 days.	Improved. +	At the eighth injection ulceration and condylomata of the tonsil healed; rash disappeared.
41	35	—	Large indurated chancre on the prepuce; adenitis; macular syphilide; congested throat.	12	12 days.	Improved. +	Rash much fainter; sore nearly healed; looked healthy; own discharge.
42	26	Sore on the prepuce for 8 weeks.	Chancre indurated on the prepuce; adenitis; profuse maculo-papular rash.	24	28 days.	Improved. +	At the seventh injection the rash was fading; at the twenty-fourth injection the rash was almost gone; the sore healed; own discharge.
43	26	Sore for 4 weeks.	Indurated chancre; adenitis; macular syphilide.	10	11 days.	— +	At the third injection the rash was fading; at the seventh injection the rash had become well marked, again deeper in colour, and more profuse; sore healed. At the eleventh injection the rash faded.
44	26	Phimosis slit up 3 months ago, not healed.	Granulating wound of the prepuce; inguinal and cervical adenitis; mascular, circular, and scaly eruption; seborrhœa.	22	31 days.	Improved. +	At the fourteenth injection the spots had all disappeared; the penis almost healed. Iodide of soda internally. Discharged for breaking the rules of the hospital.
45A	43	Phimosis *for* 4 *weeks*, concealed sore for 6 weeks.	Phimosis sore; adenitis; profuse papular syphilide.	34	46 days.	Improved. +	Sore healed; rash nearly gone; a few *scattered* papules remain chiefly on the face.
45B	—	Readmitted 25 days later; had been taking mercury pills.	Ulceration of the hard palate; a few papules on the face.	10	14 days.	Improved. +	Iodide of *soda mixture* internally as well as injections; very much better; wards to be closed.
46	27	Chancre on the penis and rash six months ago.	Ulceration of the inside of the mouth and tonsils; fading rash.	5	29 days.	—	Veins not evident, so was treated with mercurial inunctions.

SYNOPSIS OF 84 CASES OF SYPHILIS TREATED BY THE INTRAVENOUS INJECTION OF CYANIDE OF MERCURY—(*Continued*).

Secondary Syphilis in which the Primary Sore had Healed before Admission to Hospital.

No.	Age in years.	Previous history.	Nature of lesions.	No. of injections.	Time.	Result.	Remarks.
47	53	Sore on the penis 8 weeks, followed by secondaries; had been treated with mercury; gums touched. Had had dysentery in India.	Desquamating syphilide on the back, neck, head, and arms.	30	33 days.	Improved.	Blood and mucus per rectum after the fourth injection. Iodide of soda internally after the twenty-fourth injection.
48	—	None obtainable.	Phimosis, concealed chancre, adenitis, condylomata and at umbilicus, plaques on tonsils, papulo-squamous syphilide.	15	18 days.	Improved. +	After the fourteenth injection there was marked improvement, only a few spots being present, condylomata healed, phimosis reduced, no sore present.
49	25	Chancre on the penis 2 months ago, healed.	Adenitis, papulo-squamous syphilide on the trunk, arms, and legs; mucous patches in the mouth.	14	26 days.	+	A few scattered spots remain, adenitis reduced, mouth well.
50	18	Chancre on the penis 5 months ago.	Profuse general squamous syphilide, inguinal and cervical adenitis, throat injected.	36	37 days.	Improved. +	Slight staining left, no other symptom. Very bad case.
51	20		Phimosis, œdema of the penis and scrotum for 3 weeks, condylomata and *syphilitic* ulceration of the left middle finger nail, destroyed bone exposed.	48	61 days.	Improved. +	All visible signs of syphilis disappeared after 10 injections, œdema persisted; he was circumcised after the twenty-sixth injection, wound healed rapidly.
52	25	Intercourse 5 months ago; no sore now present.	Phimosis and œdema of the penis, condylomata ani et scroti, plaques in mouth and tonsils, adenitis.	15	19 days.	Improved. +	At the ninth injection the condylomata healed; at the fifteenth injection there were no signs of syphilis.
53	—	Sore on the penis had healed 14 days before admission.	Sore on the penis had broken out again and indurated, profuse macular eruption, adenitis, pains in the head.	7	8 days.	Improved. +	At the fifth injection the sore healed, the rash was fading. At the eighth injection the throat was well, the rash had faded.
54	19	Intercourse 3 months ago; has had treatment in the Infirmary.	Phimosis, concealed chancre, adenitis, profuse maculo-squamous eruption in the throat.	5	5 days.	Improved. −	Diarrhœa occurred at the fifth injection; he then had inunction. The rash had faded considerably. Discharged at own request.
55	24	Chancre and rash 6 months ago.	Otorrhœa, ulceration round the left ear and on the head, squamous syphilide on the right shoulder and chest, tonsils ulcerated.	22	22 days.	Improved. +	At the ninth injection discharge from the ear had ceased. The ulceration around the ear and on the head had healed.
56	27	—	Condylomata scroti and remains of indurated sore, gonorrhœal rheumatism.	22	22 days.	Improved. +	At the seventh injection condylomata and sore had healed. At the twenty-second injection no sign of syphilis was present.
57	33	Primary chancre 6 months ago.	Ulceration of the forehead, cheek, chin, and ear, also of the throat.	17	18 days.	Improved. +	Ulceration nearly healed, throat quite well. *Sodium iodide* was given internally. Discharged for insolence.
58	20	Chancre 6 months ago, treated for 9 weeks; has had an extensive sore on the penis.	Large ulcerating rapidly increasing mass on the dorsum of the penis, adenitis, broken down gumma in the left scapular region.	16	16 days.	Improved. +	After the seventh injection iodide of soda was given internally, sore was healing up. After the twelfth injection *the gumma healed. After* the sixteenth injection ulceration had completely healed.
59	21	Primary sore 13 months ago, treated off and on.	Sore under the surface of the penis 1 year, pigmented squamous syphilide legs.	4	13 days.	—	The veins were hard to find. Inunction was used; there was considerable improvement. Wards to be closed.
60	—	Primary sore 1 year ago.	Squamous syphilide on the penis, papular on the legs, periostitis of both tibiæ.	13	18 days.	—	Iodide of soda was given internally; an iodide rash appeared on the *seventh day*. At the eleventh injection the veins were hard to find. There was great improvement.
61	23	Sore on the penis 13 months ago, followed by profuse general eruption; discharged from Netley Hospital.	Psoriasis-like patches on both arms, back, and right leg, partly covered by scab and ulcerated. There was considerable thickening of the tissues.	27	29 days.	Improved. +	The patches had lost most of their thickening and scabs. Nearly all the colour was gone. Discharged *at his own request.*
			Rupia.				
62	45	Primary chancre 7 months ago.	Rupial spots on the thighs and arms for 6 months.	12	13 days.	Improved. +	Spots have entirely healed and are losing colour; ointment of red oxide of mercury was given for the spots.
63	20	Primary 5 months ago.	Rupial spots on both legs and shoulders, right arm, and left eyelid.	27	27 days.	Improved. +	All the rupial spots have entirely healed, leaving coppery coloured scars. Iodides were given internally and oleate of mercury ointment was applied to the spots.
64	23	Had had treatment for the last 3 months.	Rupia on the legs, nose, forehead, and scalp, ulceration of the throat, œdema of the left leg, general health bad.	7	18 days.	Improved. +	Cod-liver oil and iodides were given internally. By the ninth day the crusts had fallen off. Swelling of the face and leg had gone. His general health was much better. The veins were hard to find. Mercury was given by inunction.

SYNOPSIS OF 84 CASES OF SYPHILIS TREATED BY THE INTRAVENOUS INJECTION OF CYANIDE OF MERCURY—(*Continued*).

Rupia—(Continued).

No.	Age in years.	Previous history.	Nature of lesions.	No. of Injections.	Time.	Result.	Remarks.
65	25	Primary 3 years ago.	Remains of rupia on the back, right arm, and leg.	8	23 days.	Improved. +	Spots were healthy only pigmented; the veins were hard to find. Mercury was given by inunction.
66	60	Connexion 5 months ago.	Rupia for 3 months covering nearly the whole body, varying in size from a pea to a penny.	57	73 days.	Improved. +	Solution of perchloride of mercury was given in bath. At the fourteenth injection he was much improved; the crusts separated. On the nineteenth day iritis appeared which cleared up in a few days. At the forty-ninth injection there were no crusts; the spots were slightly coppery in colour. Very bad case.
67	28	Primary sore 18 months ago.	Rupia on the arms, back, legs, *and chest; periostitis of the* right knee and ulna and left third metacarpal bone. Very bad *case;* could not walk or stand alone. Marasmus.	47	62 days.	Improved. +	At the twenty-fourth injection the periostitis *cleared* up, leaving slight enlargement of the right knee; rupia healed and was losing colour; *cod-liver oil* and *iodides* were given internally. The patient gained 3 st. in 62 *days*.
Tertiary Lesions.							
68	33	Primary 15 years ago.	Tertiary ulceration of the scrotum; cutaneous gumma on the left thigh; septum nasi partially destroyed.	12	20 days.	Improved. +	The ulceration healed and the gumma disappeared; iodides were given internally.
69	27	Primary 11 months ago.	Gumma of the pharynx and of the scalp; tertiary ulceration of the right eyelid and eyebrow.	40	41 days.	Improved. +	Polyuria after the first few injections, but soon passed off; at the twenty-third injection the gummata had quite healed; sodium iodide mixture was given.
70	39	Primary 4 years ago.	Tertiary ulceration of the face and pharynx; necrosis of the upper jaw.	21	28 days.	Improved. +	Iodides were given internally; there was some diarrhœa. The ulceration had quite healed; there was no discharge from the jaw.
71	—	Primary 2 years ago.	Broken down gumma of the right tibia; old *pigmented* ulceration of both legs; psoriasis of the right forearm.	6	7 days.	Improved. +	Iodide of sodium was given. The ulceration became much improved.
72	23	Primary 3 years ago.	Gummatous ulceration of the inner side of the lower half of the right and left leg on and off 3 years.	7	9 days.	Improved. +	*Iodide of sodium* was exhibited. *The gumma very quickly healed.* The patient refused further treatment.
73a	25	Primary 18 years ago in India.	Gumma of the leg; syphilitic testes.	7.	10 days.	Improved. +	Iodide of sodium was given. Considerable improvement. Wards to be closed.
73b	—	Re-admitted 16 days later; he had not been taking any medicine.	Periostitis of the right tibia, pain in the knees, ulceration of the throat and face.	11	25 days.	Improved. +	The ulceration had quite healed. The throat was well and the periostitis was gone. At the eleventh injection the vein was missed so he was given mercury by inunction and iodide of sodium and cod liver oil.
74	34	Primary 7 years ago.	Chronic superficial glossitis (syphilitic).	3	27 days.	Improved.	The veins were not evident.
75	27	Primary 16 months ago.	Tertiary synovitis of both knees and ankles; throat ulcerated.	11	35 days.	Improved. +	Iodides *were given* internally; all the symptoms disappeared.
Cases not Classed who Refused Treatment or Absconded.							
76	34	—	Indurated chancre for 8 weeks; adenitis; squamous syphilide.	1	2 days.	—	The patient refused treatment.
77	22	—	Large sore on the prepuce covered by a white membrane; adenitis; profuse macular rash and lichen.	11	11 days.	—	Refused to stay in hospital; sore healing; spots fading.
78	22	Connexion (last) 2 weeks ago; rash appeared 21 days after admission.	Phimosis; concealed sore; adenitis; squamous syphilide; injections 21 days after admission.	8	28 days.	—	Circumcision was performed; the sores healed; the spots were fading; patient refused further treatment.
79	17	—	Phimosis; concealed sore; adenitis; condylomata ani.	6	7 days.	—	The patient refused treatment; absconded.
80	19	Has been treated with mercury in the out-patient department.	Phimosis; sores on the penis for 4 weeks; adenitis.	11	15 days.	—	Circumcision was performed; the patient refused treatment.
81	28	Chancre 12 months ago.	*Macular syphilide on* body; ulcers on tonsils.	14	14 days.	—	The patient refused treatment; discharged for insolence; *the spots were fading.*
82	30	—	Indurated chancre on the prepuce *for* 4 weeks; *adenitis;* macular syphilide on body.	3	4 days.	—	The patient absconded.
83	27	Primary sore 6 months ago, followed by rash.	Adenitis on both groins; papulo-squamous syphilide; ulceration of the tongue and tonsils.	3	4 days.	—	The patient refused treatment.
84	21	Sores on the penis *for* the last 2 months.	Indurated chancres; adenitis; profuse papulo-macular eruption; tonsils ulcerated.	4	5 days.	—	The patient refused to stay in hospital.

cases special attention was paid to the general health of the patient. In the tertiary and in some of the rupial cases the iodides of sodium and ammonium were used. All cases on being discharged from the wards were advised to undergo a further and prolonged course of the usual treatment in the out-patient department of the hospital. The cases are classified in the accompanying table as (1) primary and secondary lesions; (2) secondary lesions; (3) rupia; (4) tertiary lesions; and (5) cases not classified.

The patients whose cases I have described received their treatment in the wards of Mr. J. Ernest Lane and I have to thank him for his kind permission to publish the notes of the cases.

Colchester.

A CASE OF INTRINSIC CANCER OF THE LARYNX; TOTAL LARYNGECTOMY; RECOVERY.

By J. W. LEECH, M.D., B.S.DURH.,

SURGEON TO THE THROAT AND EAR HOSPITAL, NEWCASTLE-ON-TYNE.

A MAN, aged 57 years, single, consulted me on Oct. 11th, 1898, complaining of pain in the throat, accompanied by loss of voice and difficulty of swallowing of five months' duration. The history of the case was as follows. The patient who is a fine, muscular, healthy-looking man complained in March, 1898, of gradual failure of voice unaccompanied by pain. In June he complained of a constant dull aching pain which was at times intensified but was always strictly localised in the larynx. About this time the failure of phonation was complete and a month later dysphagia was a marked symptom. He had also very distressing dyspnœa on exertion, but this symptom, together with a violent paroxysmal cough which was induced by swallowing liquids or solids, did not trouble him until shortly before he consulted me. While under my observation he began to expectorate *after his attacks of* coughing a small quantity of thick glairy mucous stained with bright blood which on microscopical examination gave no indication of the grave nature of his complaint. He was slowly losing flesh. On making a laryngoscopical examination when I first saw him the cords were seen to be fairly mobile and somewhat congested but no nodule was present; this, together with his complaint of a constant sense of dryness in the throat, made me somewhat doubtful about diagnosing what his other symptoms decidedly suggested—viz., malignant disease of the larynx. A fortnight later on again examining the cords a small pearly white nodule was seen in the middle of the right cord, while in a corresponding position on the other cord a smaller nodule was just discernible. The cords, which were markedy hyperæmic, were not so mobile as when seen on the previous occasion, the right cord being the more fixed. His symptoms meanwhile had been progressively growing worse, particularly the dyspnœa, which was most distressing on the slightest exertion. He had lost more flesh and was very anæmic. There was a total absence of any sign of glandular involvement and the larynx was freely moveable. There was no venereal history. His mother had died from malignant disease of the rectum. The diagnosis was now quite simple and, having informed him of the grave nature of his disease, of the only treatment at all likely to benefit him, and of the tremendous risk of the operation as shown by the statistics quoted by Jacobson and others, he elected after some consideration to have it performed. Before proceeding with an operation of such gravity as laryngectomy I submitted the case to my friend and former teacher, Professor Arnison, who quite confirmed my views.

The operation of tracheotomy and exploration was performed on Nov. 6th. Dr W D Arnison administered chloroform and with the assistance of Professor Arnison who had kindly offered to help, I made an incision in the median line about half an inch above the upper border of the sternum right down to the trachea which was seized and pulled up. After opening the wind-pipe a Trendelenburg's tampon-tube was inserted and the tampon was freely inflated. The incision was carried upwards to the level of the hyoid bone and was deepened until the larynx was well exposed. An incision was made into the crico-thyroid membrane and the thyroid, which was considerably calcified, was snipped through with a stout pair of scissors. On drawing asunder the halves of the thyroid the growth was seen to be more extensive than had been at first supposed. It was seen to involve the whole larynx and to extend downwards for some distance. To ascertain its exact extent the cricoid cartilage and the upper three rings of the trachea were snipped through, in the course of which the isthmus of the thyroid glands was divided, but with very little hæmorrhage. The extensive origin of the growth was then clearly visible. The disease was seen to be more extensive on the right side, extending as a somewhat flat, dark-red, irregularly granular mass of very friable consistence from the whole of the under surface and part of the margin of the right cord across the upper part of the crico-thyroid membrane to the posterior portion of the left cartilage and cord; below it implicated the whole of the right and posterior surfaces of the cricoid and also the upper two rings of the trachea on the right side only, where the growth was very prominent, and projected into the lumen of the tube for about three-eighths of an inch, causing some occlusion. At this stage, as the patient's breathing which was not at any period of the operation very good became rather critical and as he showed marked symptoms of collapse, it was deemed advisable, seeing that nothing but total extirpation could afford any hope of benefit, to postpone further interference. The wound was then closed with superficial silkworm gut sutures and was dressed and the patient was put to bed. Steam impregnated with oil of eucalyptus was sprayed over the wound and hot flat sponges were applied *continuously till the more serious operation. Trendelenburg's* tampon-tube which was left in the trachea was replaced in 24 hours by an ordinary Durham's tube. On being put to bed the patient speedily responded to stimulative treatment and the improvement in his general condition was most marked. So greatly had the tracheotomy relieved the dyspnœa and the cough that he was enabled to sleep for several hours every night and to partake of nourishment by the mouth without inconvenience. The exploratory wound healed up well and there was an entire absence of chest complications.

On Nov. 17th the operation of total laryngectomy was performed. Dr. W. D. Arnison administered chloroform and Mr. N. C. Bailes and Mr. T. S. Parkinson assisted. I reinserted Trendelenburg's tampon-tube into the trachea and freely dilated the tampon. The exploratory incision was then reopened and another incision was carried outwards at right angles to this for three inches on either side at the level of the lower border of the thyroid cartilage. This incision was deepened, no muscle other than the platysma being divided until the larynx could with the aid of retractors be freely exposed. An incision in the *middle line was then* made and the larynx was re-opened, a couple of small sponges secured by silk and artery forceps being packed above the tampon. The perichondrium and its muscular attachments were then carefully dissected off in front and laterally with a raspatory, the alæ were separated from their connexions, and the thyro-hyoid membrane was cut through together with the thyro-epiglottidean and the aryteno-epiglottidean folds. The epiglottis was left moored by its hyo epiglottidean fold. The cricoid was detached from the trachea, through the sides of which silk sutures were passed and held in position by artery forceps. Having carefully cleared the cricoid in front and laterally it was seized by a pair of vulsellum forceps and pulled forwards and upwards while it was carefully separated from the œsophagus. The dissection was continued upwards till the cricoid was freed, then the two cartilages were removed, not quite *en masse*, for owing to the calcification they were very brittle and they constantly broke in the grip of the forceps. As the first two rings in the trachea were considerably diseased, which was afterwards fully confirmed microscopically, the upper three rings were next removed. The hæmorrhage, which was never excessive, was easily controlled; indeed, no vessels were tied and only four vessels required twisting. The loose tissues in front of the exposed part of the œsophagus were then freely dissected off until the muscular fibres of that tube were clearly visible. All oozing was arrested by free mopping with hot carbolic lotion of one in 60. The cavity was next sprayed out with listerine and then with a little iodoform. The trachea being secured by a couple of silk sutures passed through each side of the severed end and brought through the skin at a higher level, a small pad of iodoform gauze was interposed between the inner surface of the trachea and the silk sutures on both sides. The lateral incisions were closed with silkworm gut and the cavity was well-packed with Seabury's iodoform gauze, especially round the top of the tampon; the wound was then expeditiously dressed and the patient was put to bed again, the operation having lasted only one hour and 10 minutes. The condition of the patient being one of extreme collapse, 12 minims of solution of strychnia were injected subcutaneously; hot-water bottles were liberally applied, and an enema of two ounces of brandy and four ounces of strong black coffee was thrown up the rectum and was repeated in half an hour, and in an hour's time the great collapse symptoms had somewhat responded to the stimulation. I might state that in cleaning the front of the œsophagus I inserted a bougie almost to the cardiac orifice of the stomach in order to avoid button-holing.

After-treatment and progress.—A bronchitis kettle, the steam of which was impregnated with oil of eucalyptus was kept boiling by the bedside and the tube was covered with hot flat sponges for a fortnight. Six hours after the operation the patient swallowed iced water without any inconvenience and there was a remarkable freedom from pain. Nutrient and stimulative enemata were given every four hours until the gut became intolerant. On Nov. 18th the sputum was quite normal and the cough was by no means troublesome. The patient swallowed semi-solid food without any inconvenience. The temperature was 98·4° F. His condition was well maintained on the 19th, when the sputum was somewhat blood-stained and purulent but not copious. There was some slight pain in the wound. The superficial dressings were changed and a bougie was passed from the wound into the mouth. On the 20th there was no change. All the dressings were renewed and the cavity was repacked. The cough was not very troublesome. On the 21st the sputum was somewhat offensive, purulent, and copious, and the cough was rather troublesome, but there was no pain. The wound was redressed and the tracheotomy tube was moved from the tracheal incision to the severed end of that organ. On the 22nd the sputum was less offensive and less purulent but it was still copious. The general condition of the patient was good. This condition was well maintained on the 23rd, when the sputum was much improved. Nearly all the sloughs had now separated from the walls of the cavity. This improvement continued on the 24th, 25th, and 26th. On the 27th the condition was excellent. All sloughs had separated and the patient sat up in bed for an hour and this improved condition was well maintained on the 28th. On the 29th the cough, possibly owing to saliva and food passing through the pharyngeal fistula, was very troublesome. The dressings had to be frequently changed on this account, as they quickly became soaked. The patient's condition, however, was excellent, and he got up and had exercise in his room. On the 30th he partook of mutton cutlets, swallowing solids with more comfort than liquids. On Dec. 1st there was continued improvement. The wound was perfectly healthy, and the patient was put on ordinary diet, and this improved condition was well maintained on the 2nd and 3rd. On the 4th the patient himself changed his tube and packed the cavity. He also passed the œsophageal bougie from the wound to the mouth without discomfort or inconvenience. On the 5th the patient went downstairs. He could now dress the wound and change the tube with perfect ease, and this improvement was maintained on the 6th. On the 7th he took walking exercise in the open air for about an hour and he swallowed solids and liquids without any portion passing through the pharyngeal fistula. The patient returned to Leeds alone on the 10th with an ordinary tracheotomy tube *in situ*, and taking with him a bougie which he was instructed to pass four times a day from the pharyngeal fistula to his mouth. An attempt at fitting Stewart's artificial larynx proved unsatisfactory owing to the unsuitable nature of the instrument for this case. On the 17th the patient found that the rapid contraction of the pharyngeal orifice entirely interfered with the passage of the bougie and he therefore returned to Newcastle. When I saw him the pharyngeal fistula would barely admit of the passage of a knitting needle. Dilatation was gradually produced by passing fine urethral bougies until the orifice permitted of the insertion of a small-sized sponge tent which was left in for three hours and replaced by larger ones, after which further contraction was kept in check by the passage of full-sized urethral bougies four times a day, and on the 26th I fitted in a Guessenbauer's artificial larynx, made by Hawksley of London, in which the curves of both tubes were somewhat more pronounced than in Guessenbauer's diagram, and although it was the same length as the original an extra vertebration was added to the pharyngeal tube. The patient naturally suffered from considerable pain and inconvenience at first, but in the course of an hour the organs became more tolerant. With the reed inserted he could speak remarkably well in a loud, clear, well-voiced monotone distinctly audible at 20 yards, and when the cap was in his loud whisper could be heard 15 yards away. The irritation brought about by the apparatus caused much coughing and the reed soon became blocked. He was, however, sent to his abode in the town with the apparatus, minus the reed, in the wound. On the following day he pronounced the instrument unbearable and complained of difficulty in swallowing which he attributed to the pharyngeal tube being too long. On laryngoscopical examination the upper end of the pharyngeal tube could not be seen but the epiglottis was visible and apparently functionless. Another cause of complaint was that saliva, &c., were continually passing through the fistula, due perhaps to his not getting the obturator pushed well home. On removing the obturator and replacing it by either the reed or the cap violent coughing was very frequently induced by saliva passing into the trachea and the reed would thus speedily become blocked. The instrument was removed and was sent to a local silversmith to have certain alterations made. The artificial larynx was re-inserted after having undergone the following alterations: (1) the pharyngeal tube and the stem of the obturator were shortened for three-eighths of an inch; (2) the free end of the tracheal tube was somewhat bevelled; (3) the front plate was altered so as to present a convex instead of a plane surface to the wound (in fact, it was made identically like the front plate in Sankey's dilating tracheotomy tube); (4) the key which locked the obturator was so altered that on making half a turn more it also locked the cap and the obturator, the failure to do which indicated to the patient that he had not got them properly inserted; (5) the cap, on account of its small size, its greater frequency in use than the reed or obturator, and its liability to get lost, was secured to the front plate by a very fine silver chain; and (6) the sides of the front plate where the strings were attached were turned well forward—in fact, almost to a right angle with the plate. The object of the last-mentioned alteration was to enable the patient to fix the tracheal tube more firmly during the insertion of either the pharyngeal tube or any of the constituent parts of the instrument and consequently to lessen the irritation of the trachea by backward pressure which had been previously the cause of much distressing coughing. The pain and inconvenience were still present, but in a less degree, and swallowing was not nearly so difficult as before. After leaving the instrument in for a little time the patient became remarkably tolerant of its presence although the frequency with which the reed became blocked at first was a source of some annoyance; but this occurred less with the improvement in the coughing as soon as tolerance became established. The patient although somewhat shy of his new monotonous voice gave a recitation lasting 10 minutes just before his return home. He returned to Leeds that evening with the instrument in, having previously introduced and withdrawn it several times unaided to my complete satisfaction. Up to the time of writing the patient still complained of some discomfort and also of apparent inefficiency of the obturator in preventing saliva, &c., occasionally trickling down into the trachea. This, I consider, will eventually be overcome by the epiglottis adapting itself to the new condition.

The course of the temperature was as follows. The highest level reached was on the second day after the tracheotomy, when it was 101° F. On the day of extirpation the morning and evening temperatures were respectively 97·8° and 98·2°. On the fourth day after the extirpation (Nov. 21st) the temperature rose to 100·2°. On the evening of the 23rd it was 99·8°, but after that date it varied from 97·6° to 98·6°.

As to the microscopical appearances, on cutting and mounting sections which had been stained in bulk by the picro-carmine method the growth was seen to present the following conditions. A dense layer of squamous epithelial cells bounded the tracheal surface of the growth, the most superficial of which having taken the stain very indifferently were rather indistinct From the deep surface of this prolongations were to be seen here and there dipping into the subjacent tissues In a dense stroma of new connective tissue in which there were marked cellular infiltration and nuclear proliferation numerous squamous nests of various sizes were seen These were most abundant towards the free surface of the growth, diminishing markedly in number when followed outwards

If I may be pardoned for presuming to offer suggestions founded on the experience of one case only I would like to make the following observations 1 The advantage of an interval of time between the tracheotomy and the more serious operation which in this case at least was most marked, cannot be over estimated Not only by affording almost complete relief to the dyspnœa and to a less degree to the cough did it effect a profound improvement in the patient's general condition, but also by dividing the shock, as it were, it gave the patient time to rally under immensely improved conditions The breathing, too, under the anæsthetic on the second occasion when tolerance to the tube had been established was much more satisfactory 2 Seeing that this is an operation *par excellence* where time is of the utmost importance it is difficult to understand why in most of the recorded cases the operator has usually selected a Hahn's sponge tampon which necessitates a delay of 15 minutes for its dilatation On this account and because Trendelenburg's tube which can be immediately dilated lends itself far more readily to asepsis than does Hahn's I very much prefer the dilating tampon tube 3 The extensive nature of the growth in this case with the entire absence of glandular involvement would seem to support Semon's view of the isolation of the laryngeal lymphatics, but unfortunately Sappey's anatomical investigations, which have entirely disproved that eminent laryngoscopist's contention, compel one to admit that the question yet awaits a satisfactory solution 4 The ease with which deglutition was performed almost immediately after consciousness had been regained, the non necessity for Symond's tubes, and the entire absence of anything like the alarming hæmorrhage which is often encountered in these cases and which in this case might have been excessive, as the patient had a short stout, muscular neck, I attribute entirely to the adoption of the method suggested by Mr Henry Morris of freeing the perichondrium and its attachments with a raspatory and avoiding the severance of any muscular structure other than the platysma 5 The very low tracheotomy which was done in spite of Guessenbauer's contention to the contrary with a view to secure more ample working space was afterwards justified by the extensive nature of the growth 6 Seeing that in cases of malignant disease of the larynx attempts at sampling the growth by intra laryngeal snaring frequently prove abortive and moreover often stimulate growth, I consider thyrotomy to be infinitely preferable and that it ought to be performed in doubtful cases, as by this means the extent and nature of the disease are accurately determined and treatment can, if consent be previously obtained, be carried into effect immediately

In conclusion, I beg to acknowledge the kind services of Mr F P Parkinson who examined the growth microscopically and to thank Mr N C Bailes for the preparation of the notes on this case To nurses Duckett and Ranson I am also much indebted for their kind and skilful attention to the patient which contributed in no small degree to the success of the case

Newcastle-on Tyne

PARTURITION FOLLOWED BY A BRAIN LESION INVOLVING THE SPEECH AND CERTAIN MOTOR CENTRES.

BY R S BERRY, M R C S ENG, L R C P LOND

ON August 25th, 1898 I was called at 5 A M to a multipara, aged 36 years, who was stated by the messenger to have just been delivered of a child and to be in a grave condition I arrived at the house at 5 15 A M, where I found the following state of affairs The patient, a stout, big built woman, was lying on her left side "huddled up" and obviously in a state of collapse The extremities were cold, the face and lips were blanched, the pulse was imperceptible at the wrist, and on being spoken to the patient responded only by an inarticulate mutter, but she knew that she had someone demanding an answer from her I immediately examined the uterus and the bed in spite of the midwife's assertion (a perfectly correct one) that there had been no post partum hæmorrhage The uterus was firmly contracted, giving the usual cricket-ball sensation upon palpation per abdomen, and there was no such amount of blood upon the bed as would indicate a profuse hæmorrhage The midwife (the patient's own sister) then gave the following account of what had happened before my arrival The child, a healthy male had been born without trouble two hours previously, the placenta following shortly in a natural manner, and the patient herself had been in a condition to call for no alarm until half an hour previously to my arrival She had then suddenly become restless for a few moments throwing her limbs about, and she was blanched and unable to be roused and could not be got to speak rationally The possibility of a pulmonary embolism was the first thing that suggested itself to my mind, the notion of post-partum hæmorrhage being now excluded The collapse was extreme and I set about trying to rally the patient before attempting any further diagnosis at all She was lifted in the bed and the whole of the wet and blood stained bed clothing was removed and then she was wrapped in warm blankets and packed all round with hot bottles I gave her a stiff tumblerful of hot brandy and water by the mouth, the swallowing movements being perfectly coordinated although she remained quite apathetic to anything that was being done for her and made no attempt to help herself in any way I now made some friction over the heart and in a short time had the satisfaction of perceiving that the beats were improving in force and lessening in frequency The breathing also, which had been rapid and shallow in character, slowed down a little and became deeper *pari passu* Some improvement being maintained by the continued application of warmth and friction I examined the chest and discovered nothing abnormal with the breath sounds The apex beat was not to be felt upon the chest wall On auscultation of the heart sounds a distinct systolic murmur was plainly audible over the second right intercostal cartilage, diminishing rapidly in audibility when traced downwards and outwards towards the ordinary site of the apical beat No murmur was apparent in the pulmonary area but the second sound in both aortic and pulmonary areæ appeared to me to be blurred in distinctness, but in neither position could I discover any reduplication of that sound On careful continuance of auscultation over the aortic area I found that I could certainly separate the murmur from the true bruit of the systole—that the two sounds (the systole and the murmur) were distinct from one another although occurring simultaneously And this view was borne out by the general state of the patient who although the murmur was constant presented no signs of any incompetence in the performance of the valvular office at the aortic orifice I diagnosed a chronic endocarditis of the surface of the valves, one affecting the surface and interfering in no way with the apposition of the edges of the lunulæ and concluded that as the result of the exertion of parturition a vegetation mass had become detached and was impacted as an embolus in the brain The further progress of the case strengthened this view, for it soon became apparent that there was loss of power down the whole of the right side of the body There was no facial paralysis the most noticeable thing about the face being the totally vacuous expression, especially in the eyes, which rolled aimlessly about at intervals and when at rest gave the impression of entire apathy to surrounding objects The patient made no voluntary effort to speak nor could any answer in speech be obtained from her until between 9 A M and 10 A M (four or five hours after the seizure), when she commenced to mutter to herself one particular sound The first answer obtained from her at all was in response to the question, asked somewhat loudly and sharply after repeated failures to elicit reply, "Do you feel better?" She said shortly and distinctly, "Better," and then she began to mutter at intervals the same sound or word (it was not distinguishable as any ordinary word) as she had first been doing I remained with her, and as the day wore on it became apparent that she was wishing now and then to speak but was unable to get beyond the inarticulate mutter, until in the afternoon, when asked by myself, "Who am I?" [no answer] "Am I the doctor? she gave an affirmative gesture and said "Doctor" perfectly distinctly. I imagine, from the completeness of articulation of these two words and also from the distinctness of the muttered sound, that the lesion in no way interfered with out-going expression of thought when once that impression had framed itself into a concrete idea in the higher centres. Coordination of the speech muscles, in fact, was not interfered with, but at the same time the paralytic condition of the right side was both of a sensory and motor nature, and I could not account for the fact that motor speech coördination was perfect, that there was no facial palsy, and that the tongue was protruded (now) in the middle line on request, while the condition of the limbs was so profoundly modified from their normal state. The paralytic condition of the right side deepened and by the next morning the right-hand grasp was almost gone and there was impaired cutaneous sensation over the whole of the right limbs. The speech, however, was improving; the patient now answered questions requiring a simple negative or affirmative always correctly but after a certain amount of hesitation, as though some obstacle lay in the outward passage of her idea. Whenever she spoke voluntarily at this time she strung her sentences together coherently and with purpose, but here and there she made use of a totally outside word (always single) or for a word, no matter whether noun, adjective, verb, or what not, she occasionally substituted the original short sound which had been her first voluntary effort at speech since the commencement of the attack. Throughout this day (the second) her most marked mental phase was the evident irritability, almost amounting to anger, with which she answered after being questioned or spoken to for any length of time. And I noticed on this day that her hair which under ordinary circumstances was straight, black, and smooth, was in the erectile condition which obtains sometimes among maniacal patients. The surrounding conditions of the patient prevented, somewhat to my chagrin, my making any attempt to test her capabilities as to reading and writing, although it is certain that not much could have been elicited as to the existence of agraphia or otherwise owing to the paralytic state of the right hand and arm. The speech volition improved quickly and on the third day, although she rambled now and then, she spoke with distinctness and in spite of a little initial hesitation (this was diminishing) communicated anything which she wished to do in a comprehensible manner. By the end of a week from the onset of the attack I could discover no verbal amnesia at all and the power of the right limbs began to return. Skin sensation improved more quickly than muscular movement and she located pin-points and pain sensations accurately while the motor activity of both arm and leg was still much modified. From this time up to December she improved rapidly in every way, the mental condition being then normal and the physical weakness having cleared up to a great extent, a fair amount of difference between the right- and left-hand grasp still remaining.

I submit that the apparent discrepancy between the recoveries (in point of time) of the mental and motor states admits of a physical explanation. I believe that the impaction of the embolus was never a complete one with regard to the lumen of a vessel; that the speech centre, although for a time partly cut off from its nutrition, was never wholly so; and that the centres of movement for the limbs were the more deeply affected owing to an increased want of blood-supply. To bring this about there must either have been two emboli or one embolus impacted at a branching point of some vessel common in its origin as the feed-pipe of the speech and motor centres. I think that the latter was the more probable state and that the speech centre received throughout a supply of blood just sufficient to maintain it at a low ebb of vitality, while the motor centres from the unequal lapping of the embolus into the lumen of their feed-pipe were for a time wholly cut off from nutrition.

It seems to me that a case of this sort may afford a wide field for the consideration of the origin of idea, as to the retentive brain power for idea once originated, and as to the methods by which the doors which guard the portals of thought must be swayed before idea can become translated into action. The brain injury in this case, though an organic one in itself, was set forth and became capable of diagnosis by the functional derangements which it caused. The nutrition of the centres being interfered with the psychic functions are for the time suspended but never destroyed, for their restoration is complete when the obstacle having been removed the supply through the feed-pipe returns to its normal quantity. But though utterly dormant for a time there is no destruction of those successive psychic phases whose sequence makes up the sum of thought. Their vitality, their entity, is not destroyed, for with renewed nutrition they emerge from sleep again for all the practical purposes of life as sound as though they had passed through no ordeal at all. And, by the way, it is interesting to note how those commonest everyday notions, the efferent path of which is, so to speak, beaten broad and smooth by long use and wont, are the first to return. Initially a confused interweaving of all idea, a chaotic jumbling which gives clue to its existence only by the outward sign of a meaningless sound, but that sound a constant one, the product, say, of a telegraphic cable the operators at the central station of which are for the time being demented, the insulation between the wires of which is for the time being gone, the myriad messages of which are blurred at the outset into nothingness of meaning and emerge only as an aggregate of confusion—the powerful, case-hardened ideas whose work has forged them into irresistible forces, from babyhood onwards, cleaving their way through the chaos, thrusting aside their newer, weaker brethren and becoming cosmic as the simple negative and affirmative. Close behind these foremost leaders of idea comes the recovery of recognition of objects and persons that have through long use become part and parcel of everyday life and, lastly, the return of those infinitely numberless variations and combinations of idea which in their sum constitute what we call volition.

Are there brain cells the life-history and conditions of which differ from all others in the cell massing which constitutes our bodies, which are each separately and indelibly stamped with a concrete mould which is a thought, indestructible as the ultimate physical atom for all eternity? Once let such a theory be worked upon until it may be raised to the dignity of a scientific truth and it seems to me that a clear light may at last be thrown upon the processes of which intellect as we know it is the outcome. Injury, however trivial, to all other body cells means speedy replacement, but should such replacement be required among the brain cells after such a case as that which I have described and the mind must return to babyhood and the whole erection of the adult intellect be rebuilt from its foundations. Years upon years must elapse before complete restoration could occur and I submit that in this case the rapid return to intellectual soundness goes far to prove that idea once conceived and translatable to the world as thought is a thing which is almost incomprehensible to us by reason of its immortality.

P.S.—I imagine that the patient's early capability of replying with the words "doctor" and "better" to questions asked was merely a parrot-like imitation of the questioner, the power to frame such replies arising from the external stimulus the leading notions of which were sufficient to afford a new impress to some empty, waiting brain cell, possibly one of the right hemisphere and hence untouched by the lesion.

Southport, South Queensland.

NOTE ON A FATAL CASE OF LITHÆMIC POISONING.

BY CHARLES R. ELGOOD, M.D. LOND.

AN elderly man, aged 69 years, of thin, spare frame and of abstemious habits, suffered from five definite attacks of disease presenting the symptoms described below. The patient had passed a good deal of his life abroad; he had suffered in the "fifties" from some malarial fever which he had contracted in the East, and had had influenza five years previous to the commencement of this illness. In all other respects he had enjoyed good health. There was a strong family history of gout, though he himself had never suffered from the disease.

The dates and the duration of the attacks were as follows. The first began on June 20th, 1896, and lasted for 14 days, and the second began on Oct. 13th, 1896, and lasted for about three weeks. Recovery was not so complete after this attack as it was in the case of the others. The third attack commenced on Dec. 19th, 1896, and ended on Jan. 20th, 1897. The fourth began on March 3rd, 1897, and lasted to the end of the same month. The fifth, and last, began on June 18th, 1897, and terminated fatally on July 3rd. Each attack was foreshadowed by irritability, great restlessness, intense itching of the skin, and dyspnœa of an asthmatic type. Symptoms of violent gastric disturbance followed, there being absolute nausea. The tongue was covered with a thick white fur and epigastric pain was frequent. Anorexia was extreme. These latter symptoms were throughout so prominent and irremediable that the gastric crises of tabes dorsalis were constantly recalled to mind. The radial pulse was now observed to become exceedingly tense and cord-like, though the condition was never more than one of virtual tension, the heart force being always weak. The skin was harsh and dry. Coincident with this condition of the tongue and pulse the urine was *observed to contain a large amount of uratic sediment* and the quantity of this deposit appeared to vary with the severity of the symptoms, for as the urates ceased to be excreted the pulse relaxed to such a degree that it could with difficulty be felt, the tongue became clean, the appetite returned, the dyspnœa and itching ceased, and convalescence began. Recovery, however, was invariably slow, and was delayed by the prostration, the anæmia, and the enfeeblement of the heart with consequent œdema which the attacks appeared to cause.

On several occasions epistaxis was a prominent symptom of the attacks. Thrombosis of the right external jugular vein was present in the second attack, and thrombosis of the external saphenous vein in the third. Twice between the second and third attacks there was pain in the great toe which was thought to be due to gout. The proportion of white cells in the blood was found to be somewhat increased, and was 11 to the field. No deformed red cells were noted and the rouleaux were well formed. The spleen was not enlarged. The heart showed a certain amount of dilatation. The valves appeared healthy. There was evidence of some atheromatous degeneration of the great vessels, but on the whole the heart was not considered seriously or primarily affected. The liver was large, extending three fingers' breadth below the costal margin. It was smooth and not tender. Cough, although always a marked symptom in these attacks, was never proportionate to the physical signs, which comprised some *dulness at the right* apex and down the left back. There was moist crackling in the latter situation but no tubular breathing.

No treatment seemed to have the slightest effect on the attacks either in shortening their duration or in mitigating their severity. The patient on these occasions would subsist for days on a few ounces of milk and a little brandy-and-water. Nothing would induce him to take more. In the fifth attack the symptoms did not abate, the urates continued to be excreted, the pulse failed to relax, and then the higher nervous centres became affected as was evidenced by Cheyne-Stokes breathing, groaning, lethargy, and a gradual loss of consciousness The patient died in a comatose condition on July 3rd, 1897.

During the attacks the quantity of the urine was decreased. It varied from a few ounces below 20 ounces to a few above that number. The specific gravity was 1030. It was acid and it contained no albumin and no sugar. It was highly coloured and was passed thick and turbid from a most copious deposit of pink amorphous urates. Crystals of nitrate of urea formed immediately on the addition of nitric acid. Microscopical examination showed that the deposit consisted entirely of amorphous quadriurates, crystals of uric acid forming in abundance when distilled water was added to the specimen. No other crystals were seen. The total output of urea, which when estimated by the ureometer gave a rather higher result than when it was calculated from the specific gravity, varied from 320 to 350 grains in the 24 hours. Considering that the patient was an emaciated, elderly man, who kept his bed and took scarcely any food, this amount appeared to be greater than would have been expected. During the intervals when he was in fairly good health there was some return of diuresis. After the fourth attack when he was out of his bed but was still confined to his room he was passing 28 ounces of urine, the specific gravity of which was 1025. The urea was estimated at 350 grains. A fortnight later, and a week after all trace of urates had disappeared, he was passing 36 ounces of urine, the specific gravity of which was 1012. The urea was estimated at 250 grains. Thus the urea, apart from the question of absolute increase, was certainly not stationary, and more than this, in spite of the fact that he was on an absolutely starvation diet more of this substance was excreted during the attacks than was the case during the intervals when he took a reasonable amount of food. Numerous observations showed that the quantity of urine passed never seemed to vary so much as did the degree of its concentration. The uric acid was never estimated, but, if it be correct that in health only seven grains of this substance are excreted in the 24 hours, it must have been enormously increased, for the amorphous quadriurates could be ladled out by teaspoonfuls from every sample of urine which was passed during the attacks. Towards the end of the illness, when coma was threatening, the urine, which still preserved the above features, became sensibly *diminished in quantity*. It could not, however, be measured.

Such a condition of urine, if persistent, denotes, according to the late Dr. Ralfe,[1] a general increase of tissue metabolism throughout the body, usually accompanying or preceding some grave constitutional disturbance, and certainly in the case before us the prostration and anæmia which followed each uratic output suggested that during the attacks some increase in the molecular activity of the cells of the body was going on and so affecting the metabolism. That the excess of uric acid during the attacks was not due to disturbance of the nitrogenous equilibrium owing to the food taken is certain, for the patient took practically no food. It is also improbable that it was drawn from accumulations stored up in the system as the result of previous excesses, for he was a most abstemious man. The futility of treatment, too, recalls the cases recorded by Dr. Ralfe[2] of patients who persistently passed urine of high specific gravity containing abundance of urates and who continued to do so in spite of all treatment until some unknown cause effected an improvement in the general health. Further, the rhythmical nature of the attacks, the regular march of events in each, and their uniform duration uninfluenced by treatment, all suggest that some part in the rôle of their causation was played by the central nervous system. Dr. Latham[3] who believes that excess of uric acid is mainly due to imperfect metabolic activity of the liver-cells whereby the glycocine fails to undergo transformation, assumes that independently of the vaso-motor fibres there are various nerve fibres distributed to the cells of that organ, one set regulating the transformation of saccharine and the other that of the nitrogenous elements brought to them by the portal blood. Thus, if I understand him rightly, one might reasonably infer from the analogy of what occurs in the case of the "diabetic puncture" that it might be possible to produce an excess of uric acid by a somewhat similar lesion. We should thus have a centre presiding over the metabolic activity of the hepatic cells, and if this be so may not the activity of the cells of other organs and tissues be under a like control? Whether excess of uric acid arises from an increase or decrease of metabolism is still an open question, but given the existence of such a centre as is postulated above it appears to me to be possible that a poison such as that of malaria or influenza circulating in the blood might either stimulate it to rhythmical activity or inhibit its normal function in such a way as to produce the phenomena that are usually believed to accompany an alteration in the rate of metabolism.

That the dyspnœa, the itching, the tense pulse, and the subsequent nervous phenomena were caused by an undue proportion of urates in solution circulating in the blood is, of course, not proved and the suggestion would be made with the more diffidence when it is remembered that so high an authority as Sir William Roberts[4] has stated that the gouty may enjoy complete immunity from symptoms of any kind, though their fluids are impregnated with *biurates* to the point of saturation; and, moreover, we all know that patients with leucocythæmia pass enormous quantities of urates and never present symptoms comparable to the above. It is, however, I submit, quite conceivable in the present state of our knowledge that inappreciable changes in the condition of the blood may at one time render a poison active and at this connexion Dr. Owen Rees[5] says: "It is, of course, impossible to say how or why it is that the same urinary matters should become converted into different poisons in the blood in different diatheses; but if we turn to non-vital chemistry we find analogical results. The ferment present may differ, the fluids may vary in density or in temperature, and in the one case a poison may be produced capable of causing a violent convulsion and in the other a milder toxic agent may appear as a result causing inflammation of venous capillaries and all the phenomena of acute gout."

Lastly, the diminution of urine observed towards the close suggests that during the earlier attacks the kidneys remained sound and were enabled to excrete a sufficient amount of the urates to avert any very serious result; but later, when they were no longer able to withstand the strain, they failed to do so and a fatal dose of the poisonous material was allowed to accumulate.

Windsor.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SEPARATION OF THE LOWER EPIPHYSIS OF THE HUMERUS WITH INJURY TO THE BRACHIAL ARTERY.

BY E. WHARMBY BATTLE, M.R.C.S. ENG., L.R.C.P. LOND.,
JUNIOR HOUSE SURGEON, WARRINGTON INFIRMARY; LATE HOUSE SURGEON, MANCHESTER ROYAL INFIRMARY.

ON Nov. 7th, 1898, a boy, aged eight years, fell on his right elbow and came to the Warrington Infirmary within half an hour after the accident. The elbow was but slightly swollen and there was separation of the lower epiphysis of the humerus with backward displacement. Reduction was easy and without tendency to recurrence of the displacement. Before and after reduction no pulsation could be felt in either radial or ulnar artery at the wrist. The hand was cold and blue and there was superficial and deep anæsthesia of the hand and of the forearm up to its middle. Pressure on the fingers left a white imprint lasting for nearly half a minute. There was no pain. The limb was swathed in wool and bandaged to an internal angular splint. Three days later circulation, as judged from finger-pressure, was freer, though pulsation at the wrist was still absent. The hand was swollen and less blue than formerly. It was colder than the uninjured hand, especially after a short exposure. The anæsthesia was as before. On the 14th faint radial pulsation could be felt. The hand was less swollen, it was warmer and of better colour than before, and sensation was returning. The improvement continued and at the end of the second month there was good elbow movement.

Occlusion of the brachial artery from injury is a rare complication in fracture of the lower end of the humerus. Cases where radial pulsation is less in volume on the injured side and remains so for a short time when all displacement is rectified are sometimes seen, but even complete temporary occlusion resulting from displacement is not often met with. In the above case the facts that there was very little swelling about the joint and that after replacement of the fragments pulsation was still absent and remained so for several days point to there being a direct injury of the artery itself.

Warrington.

DAILY HÆMATEMESIS FOR OVER A YEAR.

BY MONTAGUE D. EDER, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient was a coloured woman, aged 20 years, and she was brought to me by her mistress on Oct. 7th, 1898, as she was stated to be *suffering* from phthisis. The history was briefly to the effect that for over a year she had been vomiting blood, occasionally twice a day but always once, and that in the morning, and the statement was confirmed by her mistress who had frequently been present on those occasions. The quantity varied from half a wineglassful to a tumblerful. Black motions had never been passed to the knowledge of the patient and she had never suffered from indigestion, which is a very rare complaint in this country, but she had had fever several years before. Her menstruation was regular. Her feet and hands were invariably cold. She had had much pain just below the right clavicle. She was not so anæmic-looking as most of the people in this district. Her lungs and heart were normal and her pulse was of good volume, with a pause at every eleventh beat (the significance of which I do not know), but the beats were otherwise quite regular. Her temperature was 99° F. at midday. There was no tenderness in the epigastrium. The spleen was palpable; there was no goitre. Laryngeal and ophthalmoscopic examinations showed nothing abnormal. In her right nostril or on the septum near the pharynx there was a ragged ulcer which tinged a cotton-wool mop with blood. I asked the patient and her mistress to return after breakfast and to bring with them any blood vomited in the interval. The women had ridden a four hours' journey for a consultation and were anxious to return home before dark. Two hours later they returned, bringing with them 34 fluid drachms of blood which the mistress and others had seen vomited and which was stated to be an average quantity. It had been vomited soon after a meal and was therefore very acid; it was of mammalian origin. After cauterisation of the septal ulcer with chromic acid the patient returned home. To make a second journey to this place for further treatment would have necessitated eight hours' riding on a banca road, and although I begged them to return in a few days I heard *nothing more about the case till I accidentally met the* mistress some time afterwards when I was told that there had been no further hæmorrhage. When I made the examination I did not consider that the hæmorrhage was entirely due to the ulcer. I purposely avoided quinine and other drugs. The whole population suffers from malaria and more than half from goitre or its allies. I endeavoured to exclude *malingering to which the degenerate black races are so prone.*

A CASE FOR DIAGNOSIS: ERYTHEMA?

BY EDGAR F. CYRIAX, M.B., CH.B. EDIN.

THE condition now described has been observed by me four times in the same patient—namely, in the years 1889, 1893, 1895, and 1899. *On* every one of these occasions the symptoms were the same and they followed one another in the same order, and the patient felt much better after the attack. There never were any relapses. I have searched unsuccessfully in medical literature for a description of the ailment and should be glad to hear if any of the readers of THE LANCET have met with a similar case. It was certainly not specific in origin. During the last attack my patient was also under the observation of Dr. Axel Möller, M.D. Berl., who entirely concurs in and confirms my description of the case.

The patient was a man, 20 years of age. For a few days past (i.e., since Jan. 23rd, 1899), he felt weak and disinclined to work and had considerable headache with pain on moving the eyes. He felt better on the 26th and on the 27th he declared himself to be perfectly well. On the evening of the 27th, however, he began to have a boring pain in his legs and thighs and after a very restless night he found on the morning of the 28th that locomotion was very difficult owing to pain and swelling in the left thigh posteriorly, the left calf, and to a less extent in the right calf, left forearm, and some parts of the anterior abdominal muscles. Crimson patches had appeared over the inflamed areas which stood out from the surrounding tissue and had a hard margin and consistence. Some of these patches were as large as a two-shilling piece and varied in size down to about a pin's head. These patches were sore to the touch. At about 12 noon he noticed that there was slight inflammation in the prepuce which began rapidly to swell, and by 7 P.M. the whole skin covering the penis was of a deep purple colour, the penis being now about twice its normal thickness. The swelling and discolouration had spread right up to the symphysis.

---

[5] Braithwaite's Retrospect of Medicine, vol. i., 1877, p. 41.

There was no pain in the penis. On palpation it could be made out that the skin over the penis was distended with semi-liquid blood. There were no signs of any synovitis. By 11 P.M. the extravasated blood in the skin of the penis had spread down on both sides and had filled up the scrotum so as partially to obscure the testicles. On the 29th the inflammation in the arms, legs, and thighs had given way to œdema, the penis began to shrink in size, and several bullæ filled with slightly bloody serum appeared on its surface. The patient felt much better. On Feb. 1st the penis was almost normal in size and the scrotum was smaller, but both the penis and the scrotum were considerably discoloured. New blisters here appeared in the place of the former ones which were opened. On the 2nd there was hardly any inflammation or œdema left in the arms, legs, or thighs and the hæmorrhagic patches over the inflamed areas were almost gone. On the 5th the patient was normal in every respect excepting that the skin was being renovated over the areas where the blisters had been. On the 7th new skin was completely formed over the parts where the blisters had been. The man was otherwise quite well and said that he felt "splendid."

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

KING'S COLLEGE HOSPITAL.

A CASE OF REMOVAL OF THE INTERNAL SEMILUNAR CARTILAGE OF THE KNEE.

(Under the care of Mr. BOYCE BARROW.)

OF all the articular lesions which were formerly grouped together under the title of "internal derangement of the knee-joint" probably the most important is a detachment of one of the semilunar fibro-cartilages. The immediate results of operation are probably in most cases favourable but doubts have been expressed as to the ultimate value of the joint from which the whole or a part of one semilunar fibro-cartilage has been removed. In Mr. Barrow's case recorded below five months after the operation the movements of the knee were perfect and this fact affords a complete vindication of the operation. Mr. H. Allingham has published a similar case[1] in which the patient remained quite well two years after the operation; and in a case brought before the Clinical Society of London in 1894 by Mr. C. B. Lockwood the patient could cycle freely 21 months after a partial removal of the internal semilunar cartilage, though he was afraid to play tennis. So we may conclude that, provided asepsis prevails during the operation and afterwards, there is every reason to anticipate a very favourable result from excision of a displaced fibro-cartilage of the knee. For the notes of the case we are indebted to Mr. J. R. Benson, surgical registrar to the hospital.

A youth, 19 years of age, on admission to King's College Hospital, was well-built, healthy, and much addicted to outdoor games. He complained of weakness of his left leg and said that he had had attacks of severe pain which laid him up for days together. These attacks had become frequent and troublesome of late. The history he gave was as follows. About two years ago whilst playing football he twisted his left leg and fell. It was not easy to make out the exact position of the bones at the time of the fall, but it seems that he turned sharply and rotated the leg and foot outwards as he fell. He felt at the time a severe sharp pain in the left knee and was unable to straighten his leg. After a little time this difficulty was overcome and he could extend the limb, although it was still painful. A sharp attack of synovitis seems to have followed, for the knee became swollen and tender and he was laid up for some days. Then he got about again and did not suffer any inconvenience beyond a sense of weakness in the joint. A few months later he was playing football and kicking the ground instead of the ball he again "put his knee out." This time he was not so severely injured and quickly recovered. From time to time, however, although he had no bad attacks he suffered from pain and fixation of the joint. Four months previously to admission he was jumping a ditch and twisted his leg again. It was very painful and bent up under him so that he could not extend the knee. He could flex it further but he could not get it straight. He noticed, too, that there was a small, hard lump projecting from the joint under the skin on the inner side of the knee and this seemed to him to prevent the knee going back into its place. He was carried to a medical man who reduced the deformity and then the patient was taken home to bed. The knee became very painful and swollen and ever since it had been useless to him on account of the pain and weakness. He could not walk without pain, but frequently the joint gave way and remained fixed in the flexed position, and on these occasions he generally could feel the hard lump described above.

On inspection the left leg was seen to be a good deal wasted above and below the joint and consequently the joint looked more enlarged than it really was—in fact, the measurements of both knees were nearly equal. Some fluid could be detected on palpation. Flexion and extension of the joint were free. There was also distinct lateral movement in the joint. Over the inner side of the head of the tibia was a painful spot and here a distinct depression could be felt.

The patient having been prepared and anæsthetised Mr. Barrow made a semicircular incision across the front of the left knee from condyle to condyle, extending as low in front as the tubercle of the tibia. The ligamentum patellæ was divided and the bone was turned up. When the joint was thus opened the internal semilunar fibro-cartilage was found to be detached from the tibia throughout most of its extent (especially in the front and at the sides) and folded upon itself. The lesion was so severe that any attempt at replacement was impossible. Both the cartilage and the bone had altered from the normal condition and the cartilage looked like a twisted mass of fibrous tissue. Mr. Barrow therefore dissected out the greater part of the cartilage and then he stitched up the incisions of ligamentum patellæ and capsular ligaments and the joint was closed. The superficial wound was sutured and dressed in the usual way. No drainage-tube was used. Seven days later the skin stitches were taken out, a collodion dressing was applied, and the joint was put up in light Croft's plaster splints. With regard to the after treatment, as Mr. Barrow considered that the too frequent or violent movement of the joint in such cases which is liable to occur if massage and passive movements are ordered do not benefit the part but rather tend to do harm and prolong the trouble, the joint was left in the splints for three weeks. The patient meanwhile was allowed to go about on crutches. Then he was encouraged to walk on the leg and take off the splints once or twice a day and move his limb himself, and some days later he left off the supports altogether. He left the hospital 10 days after the operation but attended as an out-patient from time to time during the next few weeks to report progress.

Remarks by Mr. BENSON.—The above case presents more interest than is usually met with in operations upon the knee both on account of the extent of the operation and of the rapidity and completeness of recovery. Before operation the patient could not work or even get about without constant discomfort and frequent attacks of severe pain which would lay him up for days together. When I saw him five months after the operation examination of his leg proved it to be as free from pain or weakness and as moveable as the sound limb. He walked quite well and had never had pain or trouble of any sort in the knee since leaving the hospital and he is now back at work with as useful a limb as ever he had.

ROYAL INFIRMARY, MANCHESTER.

A CASE OF BRADYCARDIA.

(Under the care of Dr. GRAHAM STEELL.)

BRADYCARDIA may be caused, according to Dr. J. T. Whittaker,[1] by eight conditions: (1) it may occur in certain diseases of the heart; (2) it may result from compression of the nucleus of the accelerator nerve in the spinal cord or from peripheral irritation of the vagus; (3) it may be due to organic disease of the nervous system, as in myelitis and meningitis; (4) it may occur in the course of general diseases as in convalescence after typhoid fever; (5) it may arise from various poisons, as tea or lead; (6) it may be the result of reflex irritation from the intestine; (7) it may occur in neuroses, as hysteria; and (8) it may be the result of a neuroses of the intracardiac ganglia. Perhaps the best known example of bradycardia is to be found in Napoleon the First whose pulse habitually did not exceed 40 beats per minute. Dr. Steell's interesting case is made still more interesting by the curious heart murmurs which were present. For the notes of the case we are indebted to Mr. W. J. S. Bythell, B.A., M.B., Ch.B., house physician.

---

[1] Transactions of the Clinical Society of [illegible]

A man, aged 49 years, was admitted into the Royal Infirmary, Manchester, on Oct. 4th, 1898, complaining of weakness, dyspnœa, and dizziness. He stated that he had been more or less short of breath all his life, but more markedly so during the last 11 weeks. In July last he fainted while at his work and also on two other occasions since when out for a walk. He was also very subject to attacks of dizziness which were accompanied by "shooting sensations starting in the heart and passing to the back of the head." There was no history of either rheumatism or chorea and there was nothing in the family or social history of any importance. The patient was a non-smoker and "practically a teetotaler" and attributed his illness to overwork.

On examination the patient was found to be a moderately well-nourished man with a markedly slow and deliberate temperament. There was no cyanosis or œdema, the liver was not obviously enlarged, and there was no albuminuria. On inspection and palpation the apex impulse was found to be in the left fifth intercostal space just exceeding the nipple line. The cardiac dulness extended four inches to the left and one inch to the right of the mid-sternal line and reached as high as the third left costal cartilage. The pulse-rate on admission was 40 per minute, but on no subsequent occasion was it as rapid as this, averaging from 32 to 35 beats. Neither drugs nor exertion appeared to have any effect upon the rate. The tracings showed a regular good-tension pulse. On auscultation in the mitral area the first sound with an occasional systolic murmur was distinctly heard; the second sound was also audible and was followed after a distinct interval by a well-marked diastolic murmur. An occasional faint systolic murmur was also heard at the base. There was marked epigastric pulsation and also a good deal of venous pulsation in the neck which was characterised by a peculiar triple rhythm.

A few weeks later the systolic murmur became quite constant at the apex, while the second sound was obscured by a new murmur, so as to produce a double diastolic bruit. About the end of November a still more remarkable phenomenon occurred in the form of a faint and inconstant third diastolic murmur which lasted some days. During his stay in hospital the patient did not appear to gain to any very great extent in strength, and in spite of the usual cardiac tonics and stimulants his pulse-rate remained unchanged; he also continued to show a tendency to dizziness and faintness. On the other hand, his appetite and general condition remained good and at his own request he was discharged on Dec. 28th, 1898.

Remarks by Dr. BYTHELL.—The above case of bradycardia may prove interesting in relation to the case under the care of Dr. C. Dickie Murray which was published in THE LANCET of Jan. 28th. The present case has some unusual features which make the diagnosis by no means easy. The absence of any history of rheumatism or chorea was certainly against the presence of a valvular lesion, the dyspnœa from birth and the murmurs being the only evidence in favour of mitral stenosis. The systolic murmur was of course easily accounted for by mitral incompetence, functional or organic. The case also presents some points of similarity to that under the care of Dr. Murray. In neither was there any obvious cause for the bradycardia, nor was the latter condition at all influenced by exertion or treatment. As regards the murmurs in Dr. Murray's case it seems open to question whether they were not in part at least vascular, as the diastolic was inaudible over the body of the heart itself. The venous origin of this murmur is suggested by its seat over the base of the heart and by its extending along the vessels of the neck. The systolic murmur might have been produced in the arteries, while what was apparently a diastolic murmur was in reality the continuous venous bruit, obscured during the systole by the arterial sound and becoming audible during diastole. Such at least appears to be a very possible explanation of the case and is moreover in accordance with what was found at the necropsy. In Dr. Steell's case it is impossible to speak more dogmatically with regard to the diagnosis. It is difficult to account for the sounds which were heard without assuming the presence of a valvular lesion, and the possibility of congenital disease must be borne in mind owing to the duration of the symptoms.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Administration of Definite Mixtures of Nitrous Oxide and Air and of Nitrous Oxide and Oxygen.

A MEETING of this society was held on Feb. 14th, Mr. F. J. GANT, Vice-President, being in the chair.

Dr. F. W. HEWITT read a paper on the Effects produced in the Human Subject by the Administration of Definite Mixtures of Nitrous Oxide and Air and of Nitrous Oxide and Oxygen. The investigation was based upon the following carefully recorded and timed administrations:—

	Cases.
Pure nitrous oxide	22
Nitrous oxide mixed with different percentages of air ...	107
Nitrous oxide mixed with different percentages of oxygen	102
Total	231

In each administration records were made concerning anoxæmic convulsion, cyanosis, or other changes of colour, stertor, retching movements, phonation, excitement or reflex movements, after-effects, dreams, duration of inhalation, duration of anæsthesia, quantity of gas or gases inhaled, operation performed, &c. In order to compare cases and groups of cases with one another and to ascertain to what extent certain symptoms were met with under certain mixtures arbitrary numerical values were given to the phenomena of the different administrations. By this plan it was found possible to draw up charts and to make numerous interesting comparisons not only between groups of cases but between administrations of different mixtures to the same patient on different occasions. The following were the conclusions at which Dr. Hewitt arrived: 1. When pure nitrous oxide was administered to the human subject in such a manner that no free oxygen gained admission during the administration certain phenomena arose which might be regarded as being either (1) phenomena of anæsthesia or (2) phenomena of asphyxia. 2. The anæsthetic phenomena of nitrous oxide, although apparently very different from those of ether or chloroform, were in their essential features remarkably similar. 3. The most conspicuous of the asphyxial phenomena of pure nitrous oxide were (1) embarrassed and deeply stertorous breathing; (2) cyanosis; and (3) anoxæmic convulsion. All these might be eliminated without interfering with the anæsthetic effects of the gas by administering with it certain proportions of oxygen, either pure or as atmospheric air. 4. There were other less obvious asphyxial phenomena such as wide dilatation of the pupils, swelling of the tongue and adjacent structures, and rapid cardiac action which, like the more important symptoms above referred to, might be prevented or modified by similar means. 5. Under the influence of pure nitrous oxide breathing became deeper and quicker than usual. At the end of from 55 to 66 seconds its rhythm became altered either by (1) obstructive stertor; (2) anoxæmic convulsion attacking the respiratory muscles; or (3) both conditions combined. Paralytic cessation of breathing was very rare and when it occurred was dependent quite as much upon cerebral anæmia from defective circulation as upon the presence of unoxygenated blood in the vessels supplying the respiratory centres. 6. The deep and obstructive stertor of pure nitrous oxide narcosis was not met with when employing mixtures containing moderate percentages of air or oxygen. With such mixtures only softly snoring breathing was produced.

When the percentage of air or oxygen was considerable (30 per cent of air or 13 per cent of oxygen) respiration became noiseless and free from all obstruction , 7 The most marked cyanosis was met with when very small percentages of air (from 3 to 6 per cent) or oxygen (under 3 per cent) were administered with nitrous oxide With pure nitrous oxide cyanosis might not have time, as it were, to become pronounced, for the administration might be cut short by deep stertor As the percentage of air or oxygen increased cyanosis lessened, till with 30 per cent of air it was very slight and with 11 per cent of oxygen it disappeared altogether 8 Anoxæmic convulsion, like cyanosis, was liable to be greater with small percentages of air or oxygen than with pure nitrous oxide itself and for the reason just given But as the percentages of air or oxygen increased the convulsion decreased, till with 30 per cent of air and 6 per cent of oxygen respectively it ceased to occur 9 Reflex and excitement movements were most likely to arise either with pure nitrous oxide or with nitrous oxide mixed with small percentages of air (from 3 to 7 per cent), or with nitrous oxide mixed with considerable percentages of air (from 20 to 30 per cent), or oxygen (from 10 to 20 per cent) They were least likely to assert themselves with mixtures containing moderate quantities (from 12 to 16 per cent) of air or moderate quantities (from 3 to 7 per cent) of oxygen 10 Phonated sounds were most common when nitrous oxide was administered with large percentages of air (from 12 to 30 per cent) or oxygen (20 per cent) When nitrous oxide was administered pure or with small percentages of air (from 3 to 5 per cent) they were met with to a moderate extent only Phonation was least likely to arise with nitrous oxide and air mixtures when air was present to the extent of from 6 to 10 per cent , and with nitrous oxide and oxygen mixtures when oxygen was present to the extent or from 3 to 11 per cent 11 The duration of available anæsthesia after inhalation was found to be longest after the administration of mixtures containing from 3 to 11 per cent of oxygen, the maximum duration having been attained with 7 per cent mixtures With nitrous oxide and air mixtures the resulting anæsthesia was distinctly longer than with pure nitrous oxide, but the results were very uncertain in these cases The shortest available anæsthesia was recorded with nitrous oxide alone and with nitrous oxide mixtures containing 30 per cent of air 12 In estimating the respective merits of the various mixtures used as anæsthetic agents the investigation showed that the best results were obtained with mixtures of nitrous oxide and oxygen, the next best with mixtures of nitrous oxide and air, and the worst with nitrous oxide free from air or oxygen Air was not nearly so suitable as oxygen for eliminating the asphyxial factors of a pure nitrous oxide administration owing to the large volume of useless nitrogen which must necessarily be inhaled The nitrous oxide and air cases were, as compared with those of nitrous oxide and oxygen far more uncertain in their course 13 There was no one mixture of nitrous oxide with air or with oxygen which would successfully anæsthetise every patient 14 In order to obtain the best form of anæsthesia oxygen should be administered with nitrous oxide by means of a regulating apparatus, the percentage of the former gas being progressively increased from 2 per cent or 3 per cent at the commencement of the administration to 7, 8 9, or 10 per cent , according to the circumstances of the case The longer the administration lasted the greater might be the percentages of oxygen admitted 15 The next best results to those obtainable by means of a regulating apparatus for nitrous oxide and oxygen were to be secured by administering certain constant mixtures of these two gases Mixtures containing 5 6, or 7 per cent of oxygen were the best for adult males and mixtures containing 7, 8, or 9 per cent the best for females and children 16 The next best results to those last mentioned were to be obtained by means of mixtures of nitrous oxide and air, from 14 to 18 per cent of the latter being advisable in anæsthetising men and from 18 to 22 per cent in anæsthetising women and children 17 Paul Bert whose valuable researches upon the effects produced by the inhalation of nitrous oxide and oxygen were well known, regarded an increased atmospheric pressure as essential to the production of anæsthesia by means of these gases It was clear, however, from the foregoing investigation that deep and satisfactory anæsthesia unaccompanied by any obvious asphyxial manifestations might be secured at ordinary pressures by mixtures of nitrous oxide and oxygen containing even as much of the latter gas as was present in our atmosphere 18 The last mentioned fact would seem at first sight to give a death blow to the asphyxial theory of nitrous oxide anæsthesia—a theory which supposes that this gas produces its anæsthesia by limiting or arresting normal oxidation processes within the central nervous system But because no *obvious* asphyxial manifestations made their appearance during the inhalation it was not justifiable to assume that no such interference with oxidation was taking place

Dr J S **HALDANE** after complimenting Dr Hewitt on his research, said that the paper proved that in some cases at any rate the gas had a specific anæsthetic action and that the anæsthesia was not due to asphyxia Nevertheless, in the cases where Dr Hewitt used only a small percentage of air or nitrous oxide the times for producing unconsciousness (55 seconds) corresponded with those which Dr Haldane had found to occur with the inhalation of nitrogen or hydrogen He was satisfied that it was possible to produce anæsthesia by the inhalation of pure nitrogen, but the duration of anæsthesia was too small to allow of it being usefully employed in surgery

Mr **JOHN FAIRBANK** said that Dr Hewitt's paper would be of great use to those who wished to employ the method He could fully confirm what had been said as to the advantages of the administration of combined gas and oxygen It was easy to administer and the comfort of the patient both during inhalation and during recovery of consciousness was increased Mr Fairbank also thought that there was less liability to the occurrence of spasmodic closure of the air-passages after the administration was suspended than with pure nitrous oxide

Dr R L **BOWLES** said that the subject had a great interest for him as in 1855 he was engaged with the late Dr Marshall Hall in experimenting on the subject of asphyxia with mice If mice were put into pure nitrogen or hydrogen they died in violent convulsions but if a small percentage of air, too little to allow a light to burn were mixed with the nitrogen the animal lived But if they were put into a bell jar containing pure oxygen they lived only a certain time and died poisoned by carbonic acid, although the bell jar still contained enough oxygen to make a spark of tinder incandescent He was much interested in Dr Hewitt's classification of cases of stertor which *closely corresponded with what Dr Bowles* had described to the society 39 years ago

Mr G **ROWELL** said that the truth of Dr Hewitt's conclusions would be apparent to anyone who had had experience of the method he advocated There were one or two points which were open to criticism Dr Hewitt gave as the test of the close of the period of anæsthesia the ability of a patient to respond to some simple request, such as "Open your eyes" Mr Rowell held *that the crucial point was the recollection of the request* by the patient which would not be for an appreciable time later as the patient would respond to simple directions in a reflex kind of way before consciousness was restored He thought that the length of anæsthesia depended not only on the anæsthetic given but on the amplitude and rate of respiration at the time the mask was removed If respirations were deep and rapid the anæsthesia passed off quickly He agreed that the best results were obtained by giving *oxygen in progressively increased* percentage, but next in value to that he would put the initial administration of pure nitrous oxide till the stage of excitement had passed off and then give occasional inhalations of pure air at regular intervals

Mr H. J **PATERSON** said that the behaviour of the same patient to the same anæsthetic varied on different occasions Want of sleep especially hindered the production of anæsthesia, as he had often noticed in giving gas to night nurses *As to the "analgesic borderland" before* recovering consciousness, he mentioned a case in which gas and oxygen were being administered for a long time for removal of varicose veins The administration had to be suspended and the patient talked and even sat up and looked at what was being done and appeared to feel no pain He was again anæsthetised and on recovering consciousness had not the slightest recollection of the proceedings He believed that there might be an internal asphyxia although there was no outward evidence and that the retching and the sweating which occurred [illegible] evidence of this

Dr He[illegible] he had administered nitrogen [illegible] who [illegible] the [illegible] were [illegible] identical with those of nitrous oxide anæsthesia. If 7 per cent. of oxygen were added to the nitrogen it was possible to produce sufficient anæsthesia for the extraction of a tooth. He thought that the differences observed in anæsthetising the same patient were often due to differences in the anæsthetist. Waller's experiments seemed to show that carbonic acid was not so toxic as had been believed and he found it difficult to accept the "internal asphyxia" theory as he did not see what there was to prevent the free passage out of carbonic acid. Nitrous oxide was easily absorbed by the blood and appeared to diminish the oxygen-carrying powers of the red cells and also to have a specific action on the brain.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 13th, the President, Mr. EDMUND OWEN, being in the chair.

Mr. W. WATSON CHEYNE exhibited two cases of Coxa Vara showing the result of operation. The first patient was a boy, aged nine years, who was first seen at the age of three years with deformity clearly referable to curvature of the neck of the femur and chiefly characterised by marked eversion of both legs and greatly diminished inversion. The trochanters were at the level of Nélaton's line. On Jan. 23rd, 1893, an incision was made on the outer side of one thigh at the upper part down to the bone, the femur was sawn transversely below the trochanters, and the foot and leg were forcibly inverted till the normal degree of complete inversion was obtained, and it was afterwards held in that position by an oblong perforated aluminium plate applied over the outer side of the femur at the point of division of the bones and nailed over the two fragments with nickeled tintacks so as to keep up the inversion. The wound healed by first intention. The case was shown at the Clinical Society on Nov. 24th, 1893,[1] under the title of "External Rotation of Both Legs." On Jan. 7th, 1896, the boy was admitted to Paddington Green Children's Hospital with an abscess at the seat of the former operation, on opening which the plate and tacks were found to be loose and were removed. The leg operated on was now in perfect position and as useful to him as if there had never been anything the matter with it, and the condition in the other leg had greatly improved. The second patient was a girl, aged five years, who had been more than once in Paddington Green Children's Hospital for incipient rickets and was admitted for operation in January, 1897, when three years of age. At that time there were all the signs of coxa vara in both legs; there were marked eversion of the legs (inversion even to the right angle was impossible), difficulty in abduction, and lordosis. The trochanters were at the level of Nélaton's line; there were anterior curvature of the femur and flat feet, and the child walked with a waddling gait and the knees tended to cross one another. On Jan. 26th, 1897, the right femur was divided below the trochanter, the lower fragment was inverted, and the bones were fastened together with an aluminium plate as in Case 1. Union occurred by first intention. There was now a good leg on the side operated on and also improvement in the usefulness of the other leg. The aluminium plate is still present in the leg.—Mr. JACKSON CLARKE said that he had seen the second case before operation and could confirm the great improvement in posture and gait which had been brought about. He had had four cases of the kind under his care. Of these three had active rickets at the time and were treated by the application of an instrument to keep the foot looking forward and by a perineal band, and they all improved so much that no operation was necessary. In the fourth case there was pain in the hip and it was treated by rest and extension and the symptoms subsided. In adults he thought that removal of a wedge-shaped piece of bone might be desirable.

Dr. ROBERT MAGUIRE showed a case of recovery after operation for Cerebellar Abscess. The patient, a young man, aged 27 years, was seen in private consultation on March 2nd, 1896. He had suffered from discharge from the right ear for some time and suddenly, as the result of a chill, the discharge ceased, the patient complained of pain in the right side of the head behind the ear and became rapidly comatose, showing first convulsive movements of the left side. When first seen on March 2nd he was comatose, the head was turned slightly to the right, the left arm and leg were flaccid, the mouth was turned slightly to the right, and the right pupil was larger than the left. He could be roused sufficiently to give a stupid monosyllabic answer. The temperature was then 101° F. Operation with the existing surroundings being impossible he was removed to St. Mary's Hospital in the afternoon of the same day and on arrival showed *in addition* to the symptoms mentioned distinct weakness in the right arm and leg. On March 3rd Mr. Pepper operated by trephining behind the right ear. The dura mater and pia mater and also the superficial cerebellar substance seemed to be normal, but on cutting through about a quarter of an inch of cerebellar substance an abscess was reached and about two ounces of pus were evacuated. Next day the patient was conscious and answered questions rationally. There was still a little weakness of the left side, the right side being normal. The temperature after the next two days fell to normal. Convalescence was uninterrupted and the patient was discharged cured on April 20th, 1896. He had had no bad symptoms since.—Dr. STCLAIR THOMSON asked if there was any reason why the mastoid was not opened as the infection would probably pass by way of the mastoid. If that were so and it were left it would be a source of future danger. He asked if the trephined bone had been replaced.—Dr. MAGUIRE, in reply, said that owing to the patient's condition it was considered best to relieve the abscess at once. The inflammation could not have reached the cerebellum by direct extension as both the dura mater and the surface of the cerebellum were free from inflammation. The trephined bone was not replaced.

Dr. STCLAIR THOMSON showed a case of Pharyngomycosis Leptothricia, but probably more correctly called Keratosis Pharyngis. The patient, a man, aged 38 years, showed on the faucial and lingual tonsils the characteristic appearances of what was generally termed pharyngomycosis leptothricia. The crypts of the tonsils were occupied by small, isolated, tough, firmly adherent, white excrescences which did not coalesce, and the mucous membrane beneath and between them was apparently healthy. These white masses sometimes projected above the mucous surface in the form of tufts, brushes, or stalactites. They were very adherent and generally broke off short when seized with forceps. The outgrowths recurred rapidly on being removed and the affection might be very persistent. If left untreated it generally disappeared and left no trace behind, but it is said to have lasted for five and even eight years. It was limited in distribution to the fauces. It had generally been attributed to the growth of the mycosis leptothricia. But the spores and even the mycelium thread of this fungus were nearly always present in the mouth and pharynx. The attempts of Brown Kelly to inoculate it in his own throat always failed. Dr. Thomson considered that the mycotic element was of secondary importance and that the fundamental pathological condition was a cornification of the epithelium lining the tonsillar crypts. He had found no local application of any avail.—Mr. WATSON CHEYNE asked what other structures besides organisms were present, especially if there were many epithelial scales.—Dr. DE HAVILLAND HALL agreed that the cases were of very little inconvenience except to voice-users. He had seen good results from the application of a 15 per cent. solution of salicylic acid in alcohol.

Dr. HECTOR MACKENZIE showed a case of very large Thoracic Aneurysm. The patient was a man, aged 44 years. When first seen two years ago there was no visible aneurysmal tumour, but there were dulness and pulsation in the second right intercostal space close to the sternum and sharp pain in front of the chest. He followed his ordinary occupation as a labourer and three months ago he returned with a large pulsating swelling in the upper part of the chest measuring seven inches transversely and five and a half inches vertically, while it projected two and a half inches above the surface of the chest wall. The swelling was soft. The greater part of the gladiolus and the attached cartilages on the right side had been absorbed and on palpation there was a very diffuse and heaving systolic impulse followed by a diastolic shock. No murmur was audible. The tumour had considerably increased in size in the three months during which the patient had been under observation. The case was shown on account of the exceptional size of the tumour and the comparative insignificance of the symptoms to which it gave rise.) The pain was now very much less than it was two years ago The patient did not feel ill enough to go into the hospital but he found the shortness of breath and pain produced by exertion rather trying — Dr. DE HAVILLAND HALL related a similar case now under his care at the Westminster Hospital Under treatment by rest, restricted diet and iodide of potassium the man got worse and Dr Hall was now trying a method of treatment recommended by Lancereaux, the injection into the subcutaneous tissue of the buttock of a 1 per cent solution of gelatin in normal salt solution, beginning with 50 cubic centimetres He had given five injections, the last being one of 200 cubic centimetres The injections caused little inconvenience but it was too soon to judge of their effect — Dr MAGUIRE thought that the patient had done well to refuse in patient treatment as he had never seen patients able to return to work and earn a living as this man had done after prolonged rest The recumbent posture made the aneurysm press against the œsophagus and not improbably *favoured the occurrence of rupture into that tube*

---

[1] Transactions of the Clinical Society of London, vol. xxvii.

Dr HECTOR MACKENZIE showed a man, aged 32 years suffering from Graves's Disease who showed all the usual symptoms He was admitted into St Thomas's Hospital on Jan 17th 1899, He had always been of a *nervous* tempera ment and suffered from an attack of nervous depression in 1882 About six months ago he noticed puffiness over the eyes for which he consulted a medical man and in December, 1898 he observed that his eyes were protruding and his medical attendant noticed that his throat was swollen When shown the eyes were prominent and when the patient looked down there was marked lagging of the upper lid On admission when the lids were closed they did not quite meet, but this was now diminishing The enlargement of the thyroid was considerable, soft and symmetrical The circumference of the neck was 15 inches A loud blowing systolic murmur was audible over the goitre The pulse rate varied between *90 and 120* There was marked carotid pulsation in the neck and there was a very rough systolic murmur best heard in the situation of the third left costal cartilage The disease was rare in males, the comparative frequency of the disease in this country in the *two sexes* being about one to 20 It was possible that occupation and mode of life might act as exciting causes Two of the other male patients whose photographs were shown were, like the present subject railway servants It was stated that exophthalmic goitre was not infrequent in the Russian army Occasionally in cases of this disease some substance was present in the urine which was not glucose but reduced Fehling's solution The patient showed one very interesting symptom which Dr Mackenzie had not previously observed— itching of the skin This itching had been very troublesome for some months so that the patient had "to scratch himself like a monkey" The interest of this symptom lay in the circumstance that it was not uncommonly met with during the process of treating myxœdema by means of thyroid preparation and was often a cause of a considerable amount of suffering in these cases —Mr WATSON CHEYNE said that he had operated on about 12 cases, several of them being males, removing half the thyroid Tremor and palpitation were relieved in almost all cases, so that a sempstress was able to resume her sewing and another patient was delighted because he was again able to play nap No improvement took place in the proptosis —Dr R MAGUIRE said that in cases of Graves's disease and in cases of palpitation possibly of the same nature he had found great benefit to result from the *administration* of tincture of cactus grandiflora — Dr ALEXANDER MORISON said that many of these cases improved in time irrespectively of treatment He mentioned one case which he had seen seven years ago The patient was not then put under treatment and disappeared from observation till recently when the symptoms had subsided He thought that the neurotic element was the most important and that the hypersecretion of the thyroid was secondary —Dr WILFRED HADLEY said that he had tried to follow the subsequent course of cases which had been under treatment and he thought that the symptoms often subsided in course of time In a few the nervous symptoms became more pronounced and the patients went to asylums and a *few died* from some other complaint —Dr MACKENZIE in reply, said that the mortality directly due to operation appeared to be considerable (12 per cent.) and the results were not much better than were obtained by other measures

Mr V. WARREN LOW showed a case of Subcoracoid Dislocation of the Head of the Left Humerus, with Fracture of the Great Tuberosity The patient was 51 years of age On Oct 30th of last year he slipped and stumbled down some 15 or 20 steps falling in a heap at the bottom and striking his left shoulder He did not suspect that his shoulder had been seriously injured till he arrived home and on taking off his clothes noticed that there was very considerable swelling and bruising in the region of the joint and also that the "point of his shoulder" (acromion process) was abnormally prominent Next morning it was found that the left shoulder was very considerably swollen and bruised, but that the head of the bone was absent from its normal position and could be felt below and to the inner side of the coracoid process the axis of the humerus being correspondingly altered, no signs of fracture could be detected and an unsuccessful attempt was made to reduce the dislocation He was then admitted into hospital For the next fortnight the joint was too painful to allow of any examination being made *without an anæsthetic and as the Roentgen ray* apparatus was unfortunately at this time under repair no further investigation was made the man being kept in bed with his arm on a pillow while evaporating lotions were *applied* As his arm was *absolutely useless* Mr Owen on Nov 21st cut down on to the head of the bone, using the ordinary anterior incision for excision of the shoulder joint There were quantities of soft blood clot both around and inside the joint capsule, while the following conditions were also found to be present (*a*) subcoracoid dislocation of the head of the humerus, (*b*) the great tuberosity had been completely torn from the humerus and broken into a number of small fragments, and (*c*) a small piece of the lower and inner part of the glenoid fossa had been broken off There was, however, no fracture of the surgical neck of the bone As even with the head of the bone thoroughly exposed it was impossible for some reason to restore it to its normal position Mr Owen removed the head by sawing through the surgical neck and closed the wound The man's recovery was uneventful the wound healed by first intention, and he left the *hospital* on Dec 7th *with some slight* movement between the humerus and the scapula —Mr JACKSON CLARKE related the case of an elderly woman who had had her shoulder "out" for five weeks before he saw her As reduction by manipulation *under an anæsthetic was impossible Mr Clarke* cut down and found much the same state of things as in Mr Low's case Without opening the capsule the head of the bone was pulled into place and the œdema of the arm which had been considerable before the reduction passed off About two weeks later the œdema returned and the bone was found to have slipped out of place, probably three days before Mr Clarke saw her The bone was easily replaced but the œdema did not subside no doubt because thrombosis had taken place The head of the bone was excised but the œdema persisted in spite of patient treatment and ultimately the arm had to be removed Probably it would have been wiser to have opened the capsule and wired *the fragments in the first instance*

CLINICAL SOCIETY OF LONDON.

Tuberculous Cavities in the Lung giving rise to Metastatic Abscesses —Myopathy —Results of Operation for Enlarged Prostate

A MEETING of this society was held on Feb 10th, the President Mr LANGTON, being in the chair

Mr W G SPENCER described an exceptional case of Tuberculous Cavities in the Lungs giving rise to Gaseous Metastatic Abscesses in which abscesses formed in the back in the right pleura, and in the upper part of the left thigh the latter bursting into the rectum through the great sciatic notch the disease of the lungs giving *rise to neither* symptoms nor signs The patient was a West African negro, aged 22 years who was attended by Dr Denne for pain in the left knee frequent headaches, and vomiting which he had had for eight months A large superficial
extending from the left scapula to the lowest
opened but no communication with the chest was
the patient still had fever he was admitted to
minster Hospital where a tympanitic swelling
occupying the upper portion of the left thigh and

On opening this multiloculated abscess gas and pus with a fæcal odour escaped and it was found to communicate with the pelvis through the great sciatic notch. There was no ulceration of the rectum and no infiltration of the ischio-rectal fossæ. Later the patient suddenly developed an acute effusion into the right pleura. The fluid aspirated having a fæcal odour and containing pus cells, the right pleura was consequently drained. Then followed a period in which the patient declared himself better; the abscesses in the back and the pleural wound were nearly closed and the man insisted upon getting up and asked repeatedly to be discharged. The septic fever, however, continued and foul yellow pus was discharged from the thigh in spite of frequent irrigation. All the evidence of chest disease was an occasional cough and a few râles. Yet malaria, dysentery, typhoid fever, and fæcal fistula from intestinal ulceration appeared to be clearly negatived. One day, after being five months under observation, the patient suddenly collapsed and died in four hours. Post mortem there was found a tuberculous cavity in the upper part of the right lung of the size of an orange filled by a gummy purulent fluid, whilst the rest of the right and the left lung contained numerous caseous tubercles; there was extensive tuberculous caries of the sixth, seventh, and eighth ribs in the left side and of the eighth and ninth ribs on the right side; the right pleura was thickened and adherent; and the upper part of the left thigh and buttock were completely occupied by multilocular abscess cavities. There was no tuberculous ulceration of the intestines.—Dr. KINGSTON FOWLER said that he had never met with a similar case and he asked whether tubercle bacilli were found in the cavities in the lung. He had also never before heard of fœtid collections in the pleura apart from gangrene or perforation of the lung.—Mr. G. H. MAKINS said that there must have been a mixed infection. Tuberculous abscesses were not fœtid. It was possible that the abscesses were not directly traceable to the pulmonary lesion.—Dr. J. H. BRYANT asked if any anaerobic cultures were made. In a number of cases in which there had been formation of gas the bacillus aërogenes capsulatus had been found. This occurred in one case in which the knee-joint was injured and suppurated with evolution of gas and in a case in which gaseous cavities were found in the liver, in a case of pneumothorax without perforation of the lung, and also in a case of "pneumaturia" in a diabetic patient. The bacillus coli communis had been found by Dr. Pakes in a case under Dr. Bryant's care in which there were gaseous abscesses of the liver, and he believed that they caused the evolution of gas.—Mr. SPENCER, in reply, said that colon bacilli were found in the pus of the abscesses and tubercle bacilli were demonstrated after death in the pulmonary cavities. During life there was no expectoration, and so there was no possibility of demonstrating them. He thought that the ribs had been affected secondarily to the lungs, and that the abscess in the back might have been due to extension from the rib, but that the others were metastatic.

Dr. THOMAS BARLOW and Dr. F. E. BATTEN read a paper on a case of Myopathy with Necropsy in a boy, aged five years. The patient was shown at the Clinical Society in November, 1894, and the following account of the case was given: "The boy had suffered from weakness of the back and legs since birth, he has never talked clearly, but is considered fairly intelligent, he has never had any severe illness. He was a healthy baby and nothing was noted to be amiss till the time when he should have begun to walk. No similar affection occurred in any member of the family except possibly his sister (seen by one of us, T. B.), in whom it is noted that the pectorals and deltoids are small." On admission to the hospital the following note was taken: "He is an intelligent-looking boy, his face, eyes, mouth, and tongue present nothing abnormal. His speech is of the type known as 'idioglossia.' He sits up in bed and holds the back very straight; if placed on his back he is unable to raise himself into the sitting position without turning on to his face. The child is unable to stand and the legs are flexed at the hip and knee. The muscles are everywhere very weak and thin and have a tough feeling. In the upper limbs all movements seem capable of being performed. The latissimus dorsi and pectoral muscles are very wasted; the infraspinatus is comparatively good. In the lower limb both limbs are equally wasted, no hypertrophy, all movements capable of being performed but the legs cannot be fully extended. The knee-jerks are present, equal and active. Sensation is normal to all forms, and the electrical examination shows only a diminution to both faradaic and galvanic elements." The boy developed an attack of gastro-enteritis and died. At the necropsy some defect in the arches of the lower lumbar vertebræ was found; the spinal cord and brain appeared normal. The pectoral muscles were very poorly developed, the serratus was small, the biceps was fairly developed but was pale, and the rectus abdominis muscle appeared normal. The glutei were converted into a mass of fat, and the rectus femoris was poor and thin. Microscopically no lesion could be found in the brain, medulla, and spinal cord. The anterior horn cells appeared quite normal except for the deposit of some pigment which does not usually occur in young subjects. The medullated sheath of the anterior root fibres appeared to be thinned out and not possessed of the regular contour of the normal fibres. In the muscles the following changes were found. There was extreme variation in the size of the muscle fibres, some being considerably larger than normal, and increase in the interstitial tissue between the fibres. Vacuolation was seen in some fibres and a very considerable deposit of fat between the fibres, while a fine granular (? fatty) change was found within certain muscle fibres, rendered apparent by staining in Marchi's fluid. The muscle spindles formed a striking feature in sections of the muscles and were apparently normal. The sensory nature of these organs were no longer doubtful, and it was argued that if it could be proved that these organs remained abnormal while the rest of the muscles underwent atrophy, then it was probable that the primary lesion in this disease lay in that part of the nervous system where the motor and sensory paths pursue separate routes. The authors assigned the case to the group known as the Leyden-Möbius, although hereditary history was wanting in the present case. The muscular atrophy corresponded to the late pseudo-hypertrophic type. Dr. Barlow added that when he showed the boy as a living case to the society he regarded it as a case intermediate between the form of myopathy described by Erb and the older form of pseudo-hypertrophic paralysis described by Duchenne, and Dr. Batten's investigations confirmed this view. At that time the toughness of the muscles, especially in the lower limbs, was very marked. Although there was no history of the disease in older relatives it was yet possible that others in the family might develop signs of it. Limitation of movement on the hip was so marked that some who had seen the patient were inclined to attribute the wasting in the lower limbs to some joint disease. But he felt sure that it was due to contracture secondary to the muscular weakness, particularly from having seen marked limitation of movement in one hip in a previous case of undoubted pseudo-hypertrophic paralysis where it was clearly due to muscular rigidity. He thought that the microscopic appearances supported the view that the changes were [illegible] developmental, there being a proneness to degeneration [illegible] of the muscular fibres which came on earlier in some cases than in others. The absence of the laminæ of the lower vertebræ in the present case also pointed a little [illegible] this direction.—Dr. C. E. BEEVOR thought that the [illegible] significance of hypertrophy had been exaggerated by most writers. In Meryon's cases which were published before Duchenne described the disease there was no [illegible] of hypertrophy. He thought that all forms of myopathy were essentially the same.—Dr. BERTRAM ABRAHAMS agreed that all cases of myopathy were of the same nature. The occurrence of hypertrophied and atrophied fibres in the same section of muscle was similar to a condition seen in the nerve trunks from cases of disseminated sclerosis where swollen and shrunken nerve fibres were seen side by side. He asked if Dr. Batten had found any changes in the motor nerve endings as described by Babes in his atlas.—Dr. SAVILL asked for more explicit information as to the changes in the cauda equina. He thought that there was a real nervous change in these cases affecting the lower motor neuron and not that they were not dealing with a primary muscle degeneration.—Dr. BATTEN, in reply, said that he had not examined the motor nerve endings as it was not possible to stain them in post-mortem specimens. The specimens showed slight changes in the nerve roots as they left the cord, but these could not be traced in the nerve trunks.

Mr. J. R. LUNN gave an account of some results of Operations for Enlarged Prostate. Mr. Lunn said that he had been led to perform this operation by reading the successful case recorded by Mr. Arthur Hunt in THE LANCET of Oct. 3rd, 1896. Case 1.—A man, 62 years of age, was admitted to St. Marylebone Infirmary for enlargement of the prostate and retention. The left vas was removed in May, 898, and as no improvement ensued the right testis was emoved in August, 1896. In August, 1897, the left testis as removed and considerable improvement in the frequency f micturition was experienced. In December, 1898, he eveloped dropsy and died. Case 2.—The patient was a nan, aged 63 years. In February, 1897, section of the right as was performed with some relief, and in June, 1897, he other vas was removed; a month later the patient vas able to go the whole night without emptying his ladder. Case 3.—A man, aged 63 years, had both esticles removed in January, 1897, for tuberculous disease f the epididymis. The prostate was somewhat enlarged at he time of the operation, but at the end of six months it ad shrunk in a very marked manner. Case 4.—A man, 66 years of age, had suprapubic drainage performed for retention of urine due to stricture. The prostate was felt to be nlarged. Later double castration was performed and idymin tabloids were given; he improved remarkably, but e died from diarrhœa six months after the operation. Case 5.—A man, aged 76 years, suffered from frequent micturition, &c., due to enlarged prostate. Each vas was xcised under the local influence of eucaine and the patient was greatly relieved, but he died six months afterwards from cancer of the liver. Case 6.—The patient was a man, aged 64 years, on whom double vasectomy was performed for enlarged prostate with great improvement of symptoms.—The PRESIDENT said that long before this operation was recognised he saw a patient 68 years of age who had tuberculous disease of the right testis and enlargement of the prostate. He removed the testis and when the patient returned four years later on account of similar disease in the left testis the right side of the prostate had undergone considerable shrinkage. The left testis was excised and when seen a few years later the prostate was very much smaller and the patient was very little inconvenienced. He was now 87 years of age and was able to get about comfortably. He asked whether there had been any mental symptoms following the operations.—Mr. W. G. SPENCER said that in some cases the relief to the retention and the backward pressure on the kidney appeared to have been only temporary and it seemed doubtful whether bladder drainage through a suprapubic or a perineal incision was not required as well. He asked whether there were any "eunuchoid" symptoms such as obesity, or thinning or loss of the beard.—Mr. LUNN, in reply, said that none of these cases exhibited any mental symptoms although several of them became very fat.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Extra-Uterine Pregnancy.

A MEETING of this society was held on Feb. 9th, Dr. MACNAUGHTON JONES, President, being in the chair.

Dr. BANTOCK showed two specimens of Fibroid Tumour of the Uterus, the first removed by panhysterectomy and the second by the use of the serre-nœud.

Dr. SNOW showed a Myoma removed by abdominal hysterectomy; he had adopted a new plan of dissecting off a thin layer of uterine tissue with the flaps instead of making them of peritoneum only. He also showed a small Myoma removed per vaginam.—Remarks on the specimens were made by Mr. BOWREMAN JESSETT, Dr. EDGE (Wolverhampton), Dr. WALTER (Manchester), and the PRESIDENT.

Mr. MAYO ROBSON (Leeds) read a short paper on the Complete Removal of the Fœtus and Sac in a case of Advanced Extra-Uterine Pregnancy. Leaving aside the questions of pathology and classification of extra-uterine pregnancy and also the question of treatment in the early months, he confined his remarks to the narration of a case and the discussion of the treatment of advanced pregnancy with special reference to the sac. Operation in this case was undertaken two months after full term, the fœtal movements having ceased at term. He incised the sac and removed the fœtus. Finding it would be possible to remove the entire sac he ligatured off the ovarian vessels externally and made a pedicle between the uterus and the sac internally. After separating the anterior layer of the meso-sigmoid which was expanded over the sac the tumour could be shelled out from its bed. The patient made a good recovery. Mr. Robson proceeded to quote a passage from a recent text-book to show that removal of the entire sac was not worth considering after the fourth month. Mr. J. W. Taylor in his Ingleby Lectures described the removal of the sac in intra-ligamentous pregnancy as unnecessary and dangerous. Kelly, on the other hand, advocated the removal of the sac whenever it was practicable. He would suggest the following general rules. When the fœtus was found among the intestines and had been removed, if the placenta was attached to the expanded tube it could probably be removed, but if spread over the intestines or large vessels it was safer to leave it and pack the placental area with gauze. If the fœtus was enclosed in a sac, then after extraction of the former the sac should be examined to see if its removal was practicable. The preliminary securing of the uterine and ovarian arteries would simplify the subsequent procedures. It would do no harm if very adherent portions of the sac were left if their detachment presented unusual difficulties.

Dr. MACPHERSON LAWRIE (Weymouth) read a short paper on a case of Ectopic Gestation which he recorded as a possible instance of ovarian pregnancy.

In the discussion on these two papers the PRESIDENT elicited from Dr. Lawrie that there was no critical proof that it was a case of ovarian ectopic gestation nor was it shown that any corpora lutea were contained in the tissue examined.—Mr. BLAND SUTTON emphasised the distinction to be drawn between the cases where the pregnancy was abdominal, in which the sac was formed only by fœtal membranes, and those in which it was intra-ligamentous, when the tissue of the broad ligament entered into the formation of the sac. The former were rare; he had only seen one out of 16 cases of advanced ectopic pregnancy; in these cases the sac could be removed without difficulty. But when intra-ligamentous the removal of the sac was a formidable matter and should not be attempted.—Dr. BANTOCK concurred with Mr. Bland Sutton's views. The first case he saw was one in which the live fœtus was lying within its amniotic sac in the general peritoneal cavity. The attachments of the placenta were such that any attempt to remove it must have proved disastrous. He had seen only one case of rupture into the broad ligament and the case showed that the proper treatment was opening the sac, emptying it of its contents, stitching it to the parietes and draining.—Dr. WILLIAM WALTER (Manchester) pointed out the great difference there was in operating on advanced cases of ectopic pregnancy after the fœtus was dead. To remove the sac under those circumstances was not attended by the same danger as when the fœtus was still living.—Dr. F. EDGE said he had had the pleasure of hearing Mr. Taylor deliver the Ingleby Lectures which marked a step in their knowledge of the subject. In tubo-abdominal cases it was pointed out that the sac and placenta were almost entirely tubal and that the vessels were ovarian and uterine; if these supplies were controlled the case was in the surgeon's command.—Dr. ARTHUR GILES thought the distinction between the two kinds of sac so clearly drawn by Mr. Bland Sutton was of the greatest importance. In corroboration of Dr. Walter's remarks he mentioned a case of ectopic intra-ligamentous pregnancy at five months in which the fœtus had been dead about two weeks; here he was able to remove the entire sac.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Idiopathic Dilatation of the Stomach.

A MEETING of this society was held on Feb. 9th, the President, Dr. MACFIE CAMPBELL, being in the chair.

The report of a committee to the effect "that house surgeons be allowed to charge fees for reports under the Workmen's Compensation Act and that such fee should be a guinea when the report is for an insurance company or employer of labour" was adopted.

Mr. THELWALL THOMAS exhibited a patient from whom he had removed an Epithelioma of the Larynx by Thyrotomy.

Mr. T. H. BICKERTON showed a patient, aged 51 years, on whom he had performed the "grattage" operation for severe Trachoma. The disease was of long standing, the corneæ were opaque from "pannus," and for 21 months he had been unable to follow his employment. He could only count fingers. The cornea of the right eye (the only one operated upon) was clear, and his vision was $\frac{6}{18}$ and Jaeger 8.—Dr. ALEXANDER, Mr. RICHARD WILLIAMS, and Mr. RUSHTON PARKER spoke.

Dr. T. R. GLYNN [illegible] and

Treatment of Idiopathic Dilatation of the Stomach. He considered no single symptom or symptoms as pathognomonic. Some cases originated from hyperchlorhydria. Vomiting was more particularly discussed and its absence in many cases was noted. Gastric crises and constipation or diarrhœa as a crisis of purging in the morning or as a chronic affection with much mucus in the evacuation was often present. As general symptoms neurasthenia, a flabby abdominal wall, with tendency to hernia, and moveable right kidney were mentioned. The disease was frequently met with in young men between 18 and 30 years of age. He considered that the affection occurred almost invariably in the neurotic. Treatment should be directed to the nervous system and be general rather than local. He advised caution in the use of the stomach tube.—Mr. **RUSHTON PARKER** had explored one case of dilated stomach which proved to be idiopathic dilatation, although the patient had suffered from symptoms referable to gastric ulcer. The pylorus was found to be patent and readily dilatable and the abdomen was closed. Cessation of symptoms followed this and four months later the man appeared quite well.—Dr. **ARCHER** had met with a considerable number of cases in a minor degree in young men and women. He thought irregularity of meals and want of exercise conducive to the production of dilatation of the stomach and that there was often atonic dilatation of the intestines present. He had found nux vomica and the mineral acids useful.—Dr. **IMLACH** alluded to the striking contrast in the modern views as to surgical interference.—Dr. **GILL**, Dr. **GRÜNBAUM**, Dr. **DAVIES**, and Mr. **PAUL** spoke.

Report of the Tuberculosis Committee.

The following report was presented by this committee:—

Origin of the committee.—At a meeting of the Liverpool Medical Institution held on Dec. 1st, 1898, it was unanimously resolved: "That a committee be appointed to consider what further steps can be taken for the prevention of tuberculosis in the city of Liverpool and for the treatment of the disease in the human subject and to report thereon to the institution."

Retrospective.—The committee desire to express their satisfaction that tuberculosis has declined in so remarkable a degree during the last thirty years. This diminution they attribute for the most part to the improved industrial social and moral conditions of the people and to the better sanitary state of their homes and general surroundings. The latter is mainly the result of the enlightened action of the City Council in promoting the sanitation of the city and the committee are of opinion that the extension of the same policy will tend to reduce still further the prevalence of tuberculosis. These measures have, however, been carried out with a view to the improvement of the general health of the community rather than to the prevention of tuberculosis; and their influence, though considerable, has been less conspicuous on the prevalence of this than of other forms of preventable disease. Measures adopted specially to deal with the infection of tuberculosis—namely, the inspection of the milk- and meat-supply and the enforcement of stringent regulations with regard to shippons—have been attended with obvious benefit. The reduction in the mortality from tuberculosis which has resulted from the efforts hitherto made to improve the health of the community encourages the committee to believe that a much greater and more rapid diminution might be expected to follow the adoption of further measures especially designed to cope with it, and the committee, in accordance with their instructions, have framed the following recommendations to that end:—

1. *Diffusion of information respecting tuberculosis.*—A disease which affects at least one-tenth of the population can only be adequately dealt with by enlisting the enlightened coöperation of the people themselves. The committee therefore recommend that further steps should be taken to make the people of Liverpool acquainted with the main facts concerning the nature, causes, prevention, and treatment of the disease. With this object in view they have drawn up a statement which they suggest should be widely circulated by the health authorities through suitable channels. In this statement special stress is laid on the value of fresh air and sunshine in the prevention and cure of tuberculosis and on the importance of destroying the sputa of consumptives.

2. *The arrest of tuberculosis by diminishing the sources of infection, &c.*—With regard to the organised steps which might be taken to arrest the spread of tuberculosis the committee attach the highest importance to all measures which tend to improve the sanitary condition of the people, more especially the admission of abundant air and sunlight to their dwellings. They are impressed with the very definite evidence of the advantage which has arisen from the demolition of insanitary and unwholesome dwellings and from opening up the densely populated quarters of the city. They consider that the results of the work of the corporation in this direction clearly indicate the wisdom of advancing still further on the same lines with as little delay as circumstances will allow. The committee are decidedly of opinion that the best interests of the labouring classes will be served if they are re-housed in conveniently accessible outskirts open to air and sunlight rather than in central parts of the city in the midst of warehouses and other buildings associated with increasing commerce. The committee consider that the fact should be made widely known that persons of intemperate habits succumb rapidly to tuberculous disease. The records of hospitals and workhouses furnish abundant evidence that this fatality is a direct outcome of the associations inseparable from the constant abuse of alcohol. As regards the risk of healthy persons becoming infected from consumptive patients with whom they are living, the committee trust that this will be greatly diminished by the diffusion of information as to the proper means of dealing with the sputum and by attention to the hygiene of the dwellings of the people. In those cases, however, in which the necessary precautions cannot be properly carried out it is eminently desirable that the consent of the patient and his friends should be obtained to his removal to some suitable institution where the danger of his becoming a source of infection to others would be obviated.

3. *The provision of sanatoria and special hospital accommodation.*—As regards the important question of treating those who are the subject of tuberculosis the committee are strongly of opinion that special provision is needed for them on an adequate scale. They cordially approve the suggestion that boards of guardians should establish sanatoria in some rural localities, chosen with a view to their fitness for the treatment of such cases, and that all cases of consumption which are likely to be cured or materially benefited should receive treatment therein. For those cases which offer no reasonable hope of recovery they recommend that special wards in the present union hospitals should be set apart. The problem of providing for sufferers from tuberculosis who are above the pauper class but are unable to bear the expense of the prolonged rest and change which are so essential for the treatment of consumption the committee consider has been greatly simplified by the generous donations made by Lady Willox and Mr. W. P. Hartley to the committee of the Hospital for Consumption and Diseases of the Chest for the purpose of erecting a sanatorium at West Kirby. They desire to record their high appreciation of the value of this munificent gift to the community and they trust that the sanatorium when established will receive liberal support. They are also of opinion that it is not desirable that any extensive provision should be made for the treatment of consumption in the city.

4. *Voluntary notification of infected houses and disinfection of the same by the health authorities.*—The committee have carefully considered the question of scheduling tuberculosis as a notifiable disease. They are of opinion that at present public opinion is not ripe for such a measure. They propose, however, that medical practitioners should be invited to inform the medical officer of health of cases of tuberculosis in which disinfection or other precautionary measures will, in their opinion, be attended with benefit. The medical officer of health has informed the committee that he is prepared in all cases in which the necessary consent can be obtained to carry out disinfection of the dwellings, clothing, and other effects.

Dr. T. R. **BRADSHAW** proposed, and Dr. **HOPE** seconded, the adoption of the report.—After discussion in which the **PRESIDENT**, Dr. **GILL**, Dr. **IMLACH**, Dr. **PERMEWAN**, Dr. **GLYNN**, Dr. E. T. **DAVIES**, Dr. **BUSHBY**, and Mr. **RUSHTON PARKER** took part the report was adopted.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

The Spread of Typhoid Fever.—Ligature of the Common Carotid Artery in Hæmorrhage from the Ear.—Exhibition of Cases and Specimens.

A **MEETING** of this society was held on Feb. 3rd, the President, Mr **EDWIN LEE**, being in the chair.

Dr. **SPOTTISWOODE CAMERON**, in a paper on the Spread of Typhoid Fever, took it for granted that everyone acknowledged the necessity of a specific bacterium as the cause of the disease. Sudden outbursts of typhoid fever like that at Maidstone were generally associated with the water-supply but was it not possible that in some cases a more diluted poison selecting the more susceptible individual might be responsible for some of the increased autumnal prevalences of the disease? It has been noticed in milk outbreaks that members of a family taking only a few teaspoonfuls of milk to discolour their tea escaped infection whilst those taking larger quantities raw succumbed. Might not similarly the amount taken along with the susceptibility of the individual be the determining factors of the attack in cases of slightly polluted water? Water obtained by impounding natural streams was more or less polluted. Even our uplands are not primitive deserts. Nestling in sheltered ravines upon their slopes are shepherds' and herdsmen's houses, farmsteads, pastoral and even to a slight extent agricultural. Their pastoral and bucolic inmates are not greatly concerned to protect the water-supply of the distant town. The manure heap, privy, and slope stone are there and the fall is towards the runnel making for the reservoir. The outbreak in the Tees Valley, the increased typhoid fever notifications in London following the passage of flood water over the Thames companies' filter-beds are suspicious circumstances. As to milk the insistence upon a pure and properly guarded water-supply to every milk farm would make such outbreaks rare. It was impossible altogether to ignore the possibilities of aërial convection. In a case which Dr. Cameron had recently published in the *Surveyor* he had shown how in a public institution the only common food of those attacked was milk, that the sources of the milk-supply were pure, and that the infection of the milk must have occurred in the keeping cellar which communicated with the drain. The milk could only have been infected by the passage of the poison through the

The cases were many in which the person attending atient was the *only other member of a family to be* cked by the disease. In others neighbours using *mon conveniences, especially middens, contracted* hoid fever. While in well-ventilated rooms with immeo and complete disinfection of the excreta the risk of ction was small, it was otherwise in a small cottage re an exhausted mother waited upon a child and re soiled linen was stored close to the food-supplies. épine had isolated the typhoid bacillus from soil taken n below a "disinfected" midden and Sidney Martin, days after inoculation, had been able to cultivate the illus from non-sterilised humus kept meanwhile in outer shed at a temperature varying from 3° to C. Finally, Dr. Cameron advocated (1) the thorough ection of the sources of water-supplies, and he ught it advisable that water authorities should themes own their gathering grounds; (2) the protection from tamination of the soil around dwellings and upon which houses were to be built; (3) the cremation of the *hoid bacillus as it leaves the person of the patient; and,* ecure this, (4) early notification by the practitioner even doubtful cases. He feared much that what was called nfection consisted in destroying the competitive illi and leaving Eberth's in full possession of the field.— EVANS (Bradford) pointed out that the term "aerial contion" as used by Dr. Cameron in reference to the spread of hoid fever was quite as *reasonable as* when applied to the usion of small-pox. The poisons of the two diseases are ognised as being microbic and they could therefore be veyed in the same manner. Nevertheless it must be nitted that the distance through which the germs of hoid fever may spread would be much less than the tance covered by the particulate infection of small-pox.— BARRS and Mr. A. E. A. PEARSON both thought that if ses contracted typhoid fever it was due to an imperfect infection of the hands.—Surgeon-Major ROBINSON, Dr. *ETHAM, Dr. JOHNSTONE, Dr. CHURTON, Dr. GRIFFITH,* l the PRESIDENT also joined in the discussion.

Mr. WHITEHEAD read a paper upon the Ocular Phenomena ociated with Cheyne Stokes Breathing.

Dr. STEWART related a case of Hæmorrhage from the Ear cessitating Ligature of the Common Carotid, and said at on May 18th, 1898, he was called to a child suffering m hæmorrhage from the ear. On arrival he found a girl, ed three years, lying on a sofa almost lifeless. Three eks before she had got thoroughly wet and a few days afterrds a lump appeared at the angle of the left jaw with pain swallowing. On the fourteenth day from the appearance of e swelling in the neck the child complained of intense earhe; a few hours afterwards there was a profuse discharge foul greenish pus from the left meatus, and 48 hours terwards there was an attack of hæmorrhage from the ear, llowed by another on the same day and two more on the y following. The bleeding always ended *in faintness.* . Stewart saw the child on the third day from the mmencement of the hæmorrhage, when she had another tack. He packed the external meatus with gauze and ndaged the head up tightly, but as the bleeding recurred ring the night the mother *consented* to an operation. e left common carotid was ligatured. The child was ite well within a week's time. The blood was distinctly nous in character. The only change which was noticeable ter the operation, and which still persists, was a flushing of e right side of the face with profuse sweating on exertion, compared with pallor of the left side, on which the carotid tery was tied.—Dr. TEMPEST ANDERSON, Mr. BROWN, Dr. RIFFITH, and Mr. WHITEHEAD took part in the discussion.

The following cases and specimens were exhibited:—

Dr. JENKINS: A case of Raynaud's Disease.

Mr. SIMS: Fœtal Monstrosity.

Dr. BRAITHWAITE: (1) a Dermoid Cyst; (2) an Ovarian st containing Warts; and (3) a Small Ovarian Cyst.

Mr. WARD: (1) Total Excision of the Lower Jaw (patient d specimen); (2) Skiagraphs of (*a*) Luxatio Erecta of e Shoulder, (*b*) Simple Dislocation of the Ankle without acture, and (*c*) both Wrists, one in the Early Stage of berculous Disease; (3) a case of Abscess of the Tibia eated with Dr. Robinson's Decalcified Bone-Dressing;) a case of Tenoplasty.

Dr. GRIFFITH: (1) A case of Post-diphtheritic Palsy in a an, aged 58 years; (2) Specimens from the Post-mortem oom.

Dr. CROFT: (1) Double Hydrosalpinx; (2) Fibrous and Cystic Tumour of the Ovary; (3) Sarcoma of the Uterus (*microscopic specimen*).

Mr. THOMPSON: Specimen of Gangrenous Appendicitis.

Dr. BARRS: (1) Tuberculous Lesions *of the Hands, Ears,* and Glands; (2) Œsophageal Obstruction, with Paralysis of the Left Vocal Cord; and (3) Thoracic Aneurysm.

Mr. LITTLEWOOD: (1) Gangrene of the Hand following Simple Fracture of the Forearm due to Rupture of the Ulnar and Anterior Interosseus Arteries; and (2) Ruptured Tubal Gestation.

Dr. SHARP: Specimens of Paraguay Tea.

Mr. LAWFORD KNAGGS: A case of Bony Ankylosis of the Jaw.

Dr. HELLIER: Tuberculous Peritonitis treated by Abdominal Section. (The patient was shown.)

Dr. TREVELYAN: (1) A case showing Coarse Fibrillary Contractions in the Calf Muscles; (2) a case of Affection of Speech; and (3) a case of Locomotor Ataxy in a Machinist.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—The Present Position of the Pessary in Gynæcological Practice.—Vaginal Hysterectomy for Cancer of the Uterus.

A MEETING of this society was held on Feb. 8th, Dr. J. HALLIDAY CROOM, President, being in the chair.

The PRESIDENT showed a Simple Ovarian Tumour from a patient who after its removal developed acute mania and died two days afterwards from exhaustion. This sequela of ovariotomy he believed to be unique. The mental-family history was not good. Post mortem no trace of abdominal disease was found.

Dr. J. W. BALLANTYNE read a paper on the Present Position of the Pessary in Gynæcological Practice. In order to gauge the trend of professional opinion on this subject he had examined the opinions expressed in recent *medical literature and* also the experience of instrument makers supplying the profession. From the latter source he found that there had been during the last 20 years a steady increase in the number of pessaries sold to the profession; and along with this a steady decrease in the number of varieties asked for, so that now the ring and the Hodge pessaries in one form or other and occasionally the vaginal stem with an abdominal belt constituted practically the only ones in common use. Medical men showed a marked tendency, after trying various forms of the Hodge pessary, to return to the Albert Smith modification in vulcanite, and after testing different kinds of rings to revert to the use of the simple rubber instrument containing a watch spring. More marked than the increase in the use of pessaries had been the growth in the demand for uterine curettes, especially of Martin's. The sale of these in the last six years had been remarkable *and there had been a striking decrease* in the popularity of caustic holders and instruments of that type. Intra-uterine stems were hardly ever asked for. Dr. Ballantyne then analysed the opinions expressed in 20 text-books on gynæcology published in the last 10 years. Of these eight authors were strongly in favour of this method of treating uterine displacements, five were strongly against it, and seven were critical, and even sceptical, without actually going so far as to condemn the method and banish the instruments. Different objections had been raised to the use of pessaries, *and there* was the inconvenience, as they required attention by frequent douching and occasional visits to the physician and might interfere with marital relations. Some considered even properly adjusted pessaries to be inefficient and doubted if they were ever the cause of relief from symptoms; most had no doubt at all that they never really cured in the sense of complete restoration of the normal position of the parts. Some averred that they were not only ineffective but also injurious and even dangerous; some considered all pessaries as dangerous; others only condemned the intra uterine stem, the Zwanck and the large ball pessary. *They were also credited with* being the cause of pruritus, vaginitis, ulceration, fistulæ, prevention of union of a torn cervix, subinvolution, cancer, and septic inflammation of the uterus and tubes. The supporters of their use claimed that any inconvenience or attention necessitated by the pessary was not to be compared with the trouble [illegible] n operation. Besides, they were [illegible] symptoms and sometimes longer or shorter time. Most admitted that the ordinary vaginal pessaries with ordinary care were perfectly safe; and some stated that with special care intra-uterine stems might also be considered innocuous. Opinions varied with regard to the suitability of pessaries to the different conditions. In incomplete prolapse of the uterus when the perineum could be depended on many recommended the indiarubber ring or Hodge-Smith pessary with or without transverse bars according as there was or was not some degree of cystocele. The results were that symptoms were relieved, it kept the replaced uterus in position and it gave time for the normal uterine supports to regain their tone, and if a pregnancy should occur or the climacteric be near this benefit might become permanent and a *real cure effected*. Most writers, however, believed that the benefit was only palliative and the relief temporary. The alternative treatment recommended in these cases without the use of pessaries was rest, douching, ichthyol, glycerine tampons, anterior colporrhaphy, perineorrhaphy, ventro-fixation of the uterus, or Alexander's operation. In complete prolapse where the support of the pelvic floor was lost the only possible pessary was the stem, with an abdominal belt, outside straps, and a perineal pad. The Zwanck and all instruments with hinges and screws were now generally regarded as both unsatisfactory and dangerous. For anteversions most authorities were now agreed that to try to treat anteversion of the uterus by pessaries was to use means which were inadequate to remedy a condition which was not itself productive of trouble. Anteflexion was accompanied by well-marked symptoms and the use of pessaries for its relief was narrowed down to the justifiability of employing an intra-uterine stem. All *recognised the risks of sepsis*, inflammation and perforation of the uterus. The most suitable seemed that recently introduced by Lefour which was entirely uterine without any vaginal portion. The galvanic stem was also used. In retroversions of the uterus most writers agreed that their correction by a pessary was followed by an amelioration or a total disappearance of the symptoms, also that they scarcely ever effected a permanent cure, the symptoms returning on withdrawing the instrument. The ring and Hodge-Smith pessaries were generally used for these conditions, the latter being carefully fitted to the size, shape, and curvature of the vagina.—Professor SIMPSON, Dr. HAULTAIN, Dr. CHURCH, Dr. LACKIE, and others engaged in the discussion.

The PRESIDENT read a paper on Vaginal Hysterectomy for Cancer of the Uterus. He said that the immediate risks of the operation when undertaken in circumstances at all favourable were small. Those cases which succumbed shortly after operation could only be badly selected ones, where the fornices were small, where the disease had involved the posterior wall of the bladder (a condition always difficult of diagnosis beforehand), or where sepsis had resulted; but in well-selected cases this event was seldom to be expected. A case not only to be immediately but also remotely successful must necessarily be attacked in its most early stage. A very early carcinoma of the cervix, still more an early tubular carcinoma of the body of the uterus, would, under ordinary circumstances, give an expectation of life for the patient of from 18 months to three years. With sarcoma the expectation was distinctly longer. *Out of over 200 cases of cancer he had only found 14 which were suitable cases for operation* and when the operation should have given every prospect of success. The cancer was strictly limited and in the early stage and they should have done well. Yet in all the disease returned and he believed that the women's lives had been shortened and that certainly the death was more painful than in those cases which were not operated upon. A woman's expectation of life with uterine cancer was from two to five years; the result of his experience was that with recurrence of the cancer after operation the life was shortened. *His experience in vaginal hysterectomy* for cancer had been an unfortunate one.—Dr. N. T. BREWIS, Dr. HAULTAIN, Dr. BALLANTYNE, and others took part in the discussion.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The fourth meeting of the forty-second session of this society was held at the Royal Kent Dispensary, Greenwich-road, S.E., on Feb. 3rd, Dr. Morgan Dockrell, President, being in the chair. Five new members having been elected and several members admitted, Dr. Dundas Grant read a paper on *cases of Chronic Suppuration of the Frontal Sinus and Antrum of Highmore treated exclusively through the Nose with good result*. After a few preliminary remarks as to the recognition of latent empyema of one or more of the sinuses of the nose when evidenced by free purulent discharge, often unilateral and usually accompanied by a fetor of which the patient was conscious, Dr. Dundas Grant proceeded to describe the various methods of treatment. The most generally recognised and practised was a puncture made through the alveolus of an extracted tooth extending into the antrum, through which fluids could be introduced by means of a syringe with a suitably adapted tip. For convenience of use by the patients this method was certainly superior to all others. It was originally supposed that empyema of the antrum invariably arose from disease of the teeth in this neighbourhood. This, however, was not always the case, and Dr. Grant narrated an instance of a patient with empyema of the antrum of several months' duration whose teeth were absolutely perfect. He washed out the antrum on two occasions with Lichtwitz's cannula and trocar, introduced through the inferior meatus of the nose, and was surprised to find that the patient recovered so completely that no further treatment was required. In view of such a case he was convinced that empyema of the antrum could arise from other causes than disease of teeth and that the alveolar puncture was not always called for as a method of treatment. In another case in which the alveolar puncture had been made and a tube had been introduced very little improvement took place and the suppuration persisted. The tube was then extracted and the alveolar opening was allowed to close, the antrum was washed out by means of Lichtwitz's trocar and cannula from time to time, and a complete rapid recovery ensued. This led Dr. Grant to the conclusion that the alveolar puncture was not always satisfactory, and that in point of fact it was sometimes injurious. Other cases supported this view. He considered that the presence of a communication between the mouth and the antrum was apt to lead to repeated infection of the antrum through the mouth. He brought before the meeting a patient in whom the alveolar irrigation had to be given up on account of the irritation which it produced and the absence of diminution of discharge. The treatment was carried out by means of Krause's coarse antral trocar introduced through the inferior meatus of the nose, the anterior extremity of the inferior turbinated body having been removed so as to render the introduction easy. Complete recovery resulted. The conclusion was that in the absence of obvious dental causes treatment should be carried out through the nose and that it was quite unjustifiable to extract a sound tooth so as to make an alveolar puncture for diagnostic purposes. On the other hand, if the cause was obviously dental or there was a gap in the line of teeth the alveolar puncture was by far the most convenient and desirable method of treatment. In regard to the frontal sinus he believed that the dependent position of the orifice was favourable to spontaneous recovery. The middle meatus of the nose ought to be freed by the removal of polypoid growths and it was often desirable to remove the anterior extremity of the middle turbinated body. In several instances he had brought about a complete cure by these procedures followed by the introduction of mentholised vaseline oil into the cavity by means of a suitable curved cannula. This introduction was possible in probably about 50 per cent. of cases. Naturally no such method of treatment was efficient in old-standing cases in which the frontal sinus was filled with polypoid or granulation tissue. Then the external operation was necessary, but in view of the uncertainty as to the condition of the interior of the cavity Dr. Grant insisted that a fair trial should be given to the intra-nasal methods before resort was made to this more serious proceeding.—The paper was discussed by the President, Dr. Scholefield, Mr. J. P. Purvis, Dr. Toogood, Dr. Lorimer Hart, Mr. Ernest Clarke, Mr. H. W. Roberts, and Dr. H. A. Munro.—Dr. Grant replied and the meeting then adjourned.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Feb. 10th, Dr. E. Gwynn, President, being in the chair.—Dr. F. J. Allan read a paper on Diphtheria especially in regard to the Duration of Infection and the Use of Antitoxin as a Prophylactic. In the absence or the neglect of facilities for the bacteriological examination of the throats of convalescents many cases were, he believed, allowed to mix with the healthy at much too early a stage. Fortunately the bacillus in the majority of cases lost its virulence in a week or two after the disappearance of the membrane, but it might persist in a more or less virulent state for many weeks or even months. The question then arose whether these bacilli could under favourable conditions regain their virulence, rendering such persons again infective. The New York Board of Health believed such recovery of their virulence to occur very rarely if ever, but Sir Richard Thorne and Dr. Hubert Airy maintained the "progressive development of infectivity," and Dr. D. Astley Gresswell had called attention to the "recrudescence" of diphtheria, a remarkable case having recently been reported by Golay of three recurrences of the disease in the same individual within a year, the bacilli being in the intervals non-virulent. The prophylactic use of antitoxin had not as yet made much way in this country, but in Germany and in America it was carried out extensively and with the greatest success. The position had been well expressed by Dr. Sims Woodhead: "It had been proved to the hilt that whichever agent (toxin or antitoxin) first gained access to the tissues it held the field except against the attacks of enormously greater quantities of the other. If the toxin got in first and were left unmolested for some time it could with difficulty be neutralised even by large quantities of the antitoxin, whereas small quantities of antitoxin already circulating in the fluids of the body rendered innocuous the attacks of comparatively large doses of the toxin" After narrating with much detail an instructive experience of his own in connexion with a recurring outbreak of diphtheria in a school he described the course of procedure for the diagnosis, bacteriological inspection, and elimination of the disease, remarking that with the highly concentrated sera now in the market the prophylactic dose of from 100 to 300 units was very small in volume. —Dr. Symons said that in Bath whenever a case was notified he offered to immunise the family with the consent of the medical attendant. Antitoxin treatment was most successfully carried out in their hospital.—Dr. Goodall said that he isolated adults for four weeks and children for six after the disappearance of membrane and that he immunised doubtful cases. — Dr. Bulloch said that he had been working at the bacteriology of diphtheria for seven years and was more impressed now than ever with the difficulties attending the diagnosis. The reaction was useless; Neissler's was the most trustworthy of all tests, but virulence could be determined only by experiments on the guinea-pig Three or four days were required for an absolute diagnosis Pseudo-bacilli were of many kinds and some had been cultivated up to virulence by Hewlett and Salter. He had himself found virulent bacilli in the throat six months after complete convalescence and in that of an assistant who had never suffered from the disease. Abel, too, obtained them from a toy with which a diphtheritic child had played six months before. The duration of immunity depended on the dose of antitoxin, but never much exceeded three weeks, and susceptibility was greatly a question of age. Antitoxin had no influence on the bacilli, which could be destroyed only by washing the throat with effective bactericides. Diphtheria was rarely if ever spread by means of air or water and not often by milk; the usual mode of diffusion was association of susceptible persons with others who carried in their throats bacilli which might or might not be virulent to themselves.—Dr. W. A. Bond, Dr. Christopher Childs, Dr. Willoughby, and others having spoken Dr. Allan replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 1st, Mr T. D. Pryce, President, being in the chair.—Dr. Handford read notes of three cases which had been under his care. The first was that of a girl who had been under observation for three and a half years with symptoms of Intracranial Growth. The illness commenced about eight months before admission when she woke up one morning with partial left-sided hemiplegia. Later a lump appeared in the right frontal and parietal regions which was excessively tender. She was trephined and the disease proved to be an inflammatory thickening of the bone which had pressed on the brain The skull was more than one inch thick in the area named.—Mr A. R Anderson who performed the operation spoke on the case, contrasting the use of the trephine and forceps with that of the mallet and chisel. He considered that the shock of operation was much less with the former than with the latter.—Mr. Willis said that he had had the privilege of seeing the case before operation through the kindness of Mr. Anderson and he expressed at that time the opinion that the disease was one of inflammation in the bone, arriving at this conclusion from the excessive tenderness of the bone which amounted to agony when gently tapped with the finger. The operation produced marked improvement in the symptoms and general condition of the patient who was shown.—Dr. Handford's second case was one of some obscurity but was thought to be Actinomycosis of the Transverse Mesocolon. The patient was a man who was admitted to hospital in August, 1898, with abdominal pain and diarrhœa. During his stay in the hospital he wasted rapidly, losing four stones in weight in six or eight weeks; he also had repeated rigors and jaundice on one occasion which lasted 24 hours only. An exploratory cœliotomy was performed and a large mass was discovered about the head of the pancreas, the intestines being matted together. Nothing could be done and the wound was closed. He died and the necropsy revealed a large dense mass of fibrous tissue in the transverse mesocolon, with numerous scattered abscesses. Ulceration had taken place from without into the stomach. The ray fungus was not able to be demonstrated beyond doubt in any of the pus.—Mr. A. R. Anderson spoke on this case, he having operated, remarking that he had no doubt that the disease was actinomycosis. He had operated on about 12 cases of this disease now and had been present at necropsies on several other cases, and his experience warranted his opinion of the nature of the disease, even in the absence of any discoverable ray fungus.—Dr. Handford's third case was that of a lad who had been treated for five weeks at the General Hospital for Chronic Gastric Ulcer of which disease he had the classical symptoms. He much improved and was sent to the convalescent home. Shortly afterwards he was re-admitted with abdominal pain, distension, vomiting, and a febrile temperature. Tuberculous peritonitis was diagnosed and Mr. A R. Anderson performed cœliotomy, the diagnosis being verified. The patient soon afterwards died. Dr. Handford suggested that he had become infected with tuberculous milk during his stay in the convalescent home, his diet having consisted of milk at that time, and that he had the more readily become a victim to the disease on account of his old long-standing gastric trouble.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held at St. Bartholomew's Hospital on Feb. 10th, Professor Alexander Macalister, F R S, President, being in the chair.—Mr C. B. Lockwood gave a lantern demonstration of a Suprarenal Structure found in the Inguinal Canal and showed several specimens with such bodies attached to the spermatic cord which had been mistaken for hernia. The explanation of the position in which those structures occurred was to be found in the close relationship between the suprarenal and Wolffian bodies in an early stage of the human embryo.—Mr Cecil H. Leaf exhibited specimens and drawings of the Liver, hardened *in situ*, showing the so-called Riedel's lobe Mr. Leaf held that it was not a lobe in any strict sense of the word, but merely a localised prolongation downwards of the anterior margin of the liver in the neighbourhood of the tenth costal cartilage. It occurred much more frequently in women than in men and in all degrees of development. It might be very slight—a common condition—or long and linguiform, reaching several inches below the costal margin, and in such forms simulating floating kidney. It did not appear to occur in children and was probably caused by pressure—Professor F. G. Parsons and Dr. G. F. Rogers showed specimens of Abnormal Lobulation of the Liver. The lobulation did not answer to any division known to comparative anatomists—Mr. H. J. Waring showed a specimen in which the Cystic Duct which was much dilated joined the Common Hepatic Duct in the neighbourhood of the Duodenum so that the common bile-duct was extremely short—Mr. R H. Burne drew attention to the extremely anomalous arrangement of the bile-ducts in the common otter. The cystic and hepatic ducts formed an elaborate network, recalling the arrangement found in certain reptiles—Dr. A. Keith brought forward Evidence to show that the Forms of Liver found in Man and the Higher Primates was adaptative to the Upright Posture.—Professor Arthur Thomson laid before the meeting Specimens and Drawing showing several minor fissures on the Under Surface of the Right Lobe of the Human Liver which were constant in occurrence and had been regarded as pathological. These fissures were represented in the liver of the gorilla by deep continuous fissures and were also much more marked in the human fœtus.—Dr. G. F. Rogers showed a specimen in which the Musculo-cutaneous Nerve was absent and also the Pedal Part of the Anterior Tibial, their places being supplied by branches from the saphenous nerves.—Dr. E. Barclay Smith showed a specimen of Divided Parietal Bone and reviewed the literature of this rare abnormality.

Pathological Society of Manchester.—A meeting of this society was held on Feb. 8th, Dr. R. B. Wild, President, being in the chair.—Dr. Trevelyan (Leeds) read a paper on the Diphtheria Bacillus, based on the examination of suspected exudation in the laboratory of the Leeds Medical School. He thought that the aggregation of the protoplasm in certain parts of the microbe was more characteristic than any arrangement of the micro-organisms in regard to each other. The short bacillus had been comparatively rarely found in these examinations but mixed forms were often present. Occasionally anomalous forms in the shape of long and short clubs had been obtained, but this no doubt depended largely on the nutrient medium used. Branching forms had not been seen, cultivation on white of egg usually yielding the long form. Neisser's method of staining required manipulation and perhaps the help to be obtained from it in doubtful specimens, especially of the short bacillus, is hardly as great as was at first expected. The serum media are of such value in the cultivation because the diphtheria bacillus outgrows other microbes, at least within the first 24 hours, but the cultivation can be continued on other media equally well. The growth obtained on antitoxic serum was sparse. Grown on alkaline litmus lactose agar, typical forms did not always produce acid. This acid production, especially in glucose media, could not be of great value in the rapid diagnosis. The characters of the diphtheria colony were then discussed and illustrated by drawings and impression and other specimens. The colony is frequently thicker in the centre but sometimes also round its margin. The slightly irregular margin and its somewhat dry aspect and loose attachment to the medium are important characteristics, but it is not always possible to recognise it with certainty. Finally, Dr. Trevelyan expressed the opinion that the bacteriological examination is of great importance to the clinician in not an inconsiderable number of cases, yet if the full value is to be obtained the results must be promptly communicated, thus in the large majority of cases it is possible to report by telephone or other means within 24 hours of receiving the specimens.—Professor Jones and Dr. Kelynack showed preparations of a Sarcoma of the Left Kidney which had been successfully removed by lumbar nephrectomy from a man, aged 50 years. The chief symptoms had been hæmaturia and pain. The growth consisted of a very vascular myxo-sarcoma involving almost the whole of one end of the organ.—Mr. Wright and Mr. Coates described an unusual case of Diverticulum of the Bladder not due to obstruction.

British Laryngological, Rhinological, and Otological Association.—A meeting of this society was held on Jan. 27th, the President, Dr. J. Middlemass Hunt, being in the chair.—Mr. Lennox Browne showed a case of Laryngeal Epithelioma of at least two and a half years' duration which had not been submitted to operation. The patient was a man, aged 63 years. His principal symptom was loss of voice which had occurred suddenly about four and a half years ago and had persisted. On laryngoscopic examination the left vocal cord could not be seen, but the whole of the tissues on the left side were immoveable and presented the appearance of a large, irregular mass with heightened colour and warty surface. The right cord was involved but it moved freely. The laryngeal outskirts were much infiltrated. No glands could be detected externally, but a slight spreading outward of the left thyroid ring could be felt. There was no evidence of syphilis.—Dr. Macintyre (Glasgow) and the President were inclined to doubt the diagnosis.—Mr. Bark (Liverpool) read notes of a case of Cyst of the Laryngeal Ventricle.—Mr. Stoker read a paper on the Curative Treatment of Laryngeal Phthisis. Starting with the belief that laryngeal phthisis was due to the presence of micro-organisms or the toxins they produced, he suggested that a culture should be taken from the affected part, an oxidised toxin made and applied frequently. He preferred the term "oxidised toxin" to "antitoxin," as he contended that the most potent factor in bringing about such a change was the process of oxidation. He described in detail his method of preparing the oxidised toxin.—Dr. Barclay Baron (Bristol) opened a discussion on the Value of General Treatment in Diseases of the Throat, Nose, and Ear. He reviewed the treatment of tuberculosis and more especially phthisis laryngea during the last few years and contrasted the striking difference in the general treatment adopted 25 years ago and that carried on at the present day. With regard to syphilis, he thought that larger medicinal doses should be given in the tertiary stages than appeared to be given in England. In the treatment of diphtheria he paid a tribute to the value of antitoxin. He thought the profession at large did not thoroughly realise that many cases of acute tonsillitis were rheumatic and yielded markedly to the salicylates.—The discussion was continued by Mr. Wyatt Wingrave, Dr. R. H. Woods (Dublin), the President, and others.

West Penwith Medical Society.—A meeting of this society was held at Penzance on Feb. 8th, Dr. J. B. Montgomery, the President, being in the chair.—It was decided to support the objects of a resolution passed by the Liverpool Medical Institution relative to the Vaccination Act (1898), of which a copy had been sent with a letter.—Mr. W. S. Bennett introduced a discussion on the Treatment of Abortion. In his opinion the treatment ought to be rapid dilatation of the os with the finger and removal of the uterine contents as far as possible without instruments.—Mr. A. T. Jago, Mr. C. S. Jago, Mr. Symons, and Mr. Palemon Best took part in the discussion.—Mr. John Symons described a case of Rupture of the Duodenum following a Blow on an Empty Stomach. There was no external bruising and no vomiting, but the patient's temperature rose to 104° F. Post mortem it was found that there were universal peritonitis with much adhesion of the intestinal coils and some partially digested food behind the liver.—Mr. Symons also described a series of cases of Fracture of the Skull.—Dr. Hugh M. Montgomerie related a case of Complete Recovery from Severe Chronic Dysentery in which rest, milk diet, and salicylate of bismuth were the principal treatment. He also showed a Gall-stone removed from the sister of the patient who suffered from dysentery and described a case of Choroido-Retinitis occurring in a man who had two brothers also partially blind and another one with lateral sclerosis of the spinal cord.—The honorary secretary, Mr. Evershed, resigned his office owing to departure from the town and Mr. R. D. Boase was elected temporarily in his stead.

South-West London Medical Society.—A meeting of this society was held at Lavender-hill, S.W., on Feb. 8th, Dr. Duke being in the chair.—Dr. Arkle read a paper on Some Points in the Treatment of Tuberculosis. He said that specific there was none, but probably of all remedies the "open-air" method of treatment was the most popular and the most successful. He now felt more certain than he did some years ago that the method can be worked well in the British Isles. The preparation and "hardening" of the patient was a *sine quâ non*, for tuberculous patients were generally "hot-house plants" and required to be taught to be more Spartan in their mode of life. Then they could live in the open air, for their bedroom windows would be widely open at night, and they would spend their days out of doors. Attention was called to this preparation as carried out at Falkenstein and other Continental sanatoria, especially the method of daily sponging the body, at first with pure spirit, then diluted more and more till cold water only was used. Various methods of relieving symptoms and of improving the nutrition were mentioned. In conclusion Dr. Arkle urged that the early and oft-repeated examination of the sputa was a most important element in treatment as it was in diagnosis, for the disease was generally considerably in advance of the ordinary physical signs.—A discussion followed in which Dr. Duke, Dr. Mackintosh, Mr. Ryan, Major Mark Robinson, I M.S., Dr. Barkwell, Mr. Gay, and Mr. J. B. Howell took part.

Plaistow and Canning Town Medical Society.—A meeting of this society was held on Feb. 9th at The Hall, Balaam-street, Mr. Buksh being in the chair, to hear an address by Dr. Biernacki on the Systematic Treatment of the Commoner Fevers.—The speaker, dealing with the severe types of these diseases, pointed out that the general morbid condition was induced by poisonous substances circulating in the blood. He then traced the genesis of these poisons, specific and non specific, in order to elicit rational methods of retarding their formation In the latter part of his address these methods were reviewed and stress was laid on the fact that if employed consistently from the outset they had a considerable influence in diminishing the toxic elements in the blood The neutralisation of the specific poisons by means of antitoxin was also touched upon, Finally, a point was made of the great importance of maintaining excretion Dr Biernacki throughout his address deprecated a too great reliance upon treatment by drugs alone, and threw doubt on the efficacy of many drugs commonly used Those having a prejudicial effect on excretion were condemned, and in this regard the danger of the exhibition of digitalis in heart failure associated with febrile oliguria received special attention A general discussion followed in which the particulars of several cases were adduced and the meeting closed with a hearty vote of thanks to Dr Biernacki

BRISTOL MEDICO CHIRURGICAL SOCIETY. — The fifth meeting of the session of this society was held in the medical library of University College, Bristol on Feb 8th, Dr Roxburgh being in the chair —Dr F H Edgeworth showed a specimen of Abscess of the Brain —Dr J O Symes read a paper on the Bacteriology of some Suppurations Complicating Pulmonary Disease —Dr Michell Clarke Dr Cave, Dr James Swain, Mr R Williams, and Dr Elliott discussed the paper —Dr Michell Clarke read a paper on Some Cases of Apoplexy illustrated by lantern slides showing numerous temperature charts —Mr. T Carwardine showed microscopic and lantern slides illustrating Paget's Disease — Mr R Williams spoke on the subject —Mr W H Harsant read notes on a case of Actinomycosis and illustrated his paper with microscopic and lantern slides —Dr Waldo made some remarks on the treatment of the disease —Professor Edward Fawcett showed a large number of lantern slides of sections of the Cord, Medulla, and Mid brain stained by a modification of the Pal Weigert method

Reviews and Notices of Books.

Sanatoria for Consumptives in Various Parts of the World. By F RUFENACHT WALTERS M D, M R C P Lond, Physician to the North London Hospital for Consumption and Diseases of the Chest London Swan Sonnenschein and Co 1899 Pp 374 Price 10*s* 6*d*

THE publication of this book is certainly opportune, appearing at a time when interest is so actively taken in the nature and treatment of pulmonary tuberculosis In order to give our readers an idea of the full scope of the work we may quote the title-page in full "Sanatoria for Consumptives in Various Parts of the World (France, Germany, Norway, Russia, Switzerland the United States, and the British Possessions), a Critical and Detailed Description, together with an Exposition of the Open air or Hygienic Treatment of Phthisis, with an Introduction by Sir Richard Douglas Powell, Bart, M D F R C P ' It is obvious therefore that Dr. Walters set himself a very difficult task and he has accomplished it in a most praiseworthy manner

In the first chapter the author describes what he means by "Sanatoria for Consumptives He defines them as "establishments for the open air treatment of presumably curable cases of consumption under medical direction, mainly by hygienic and educational measures They are not intended for patients whose prospects of recovery are small, nor are they intended for non tuberculous cases or for those who are merely out of health We consider this definition a good and full one It might be recommended with advantage to the managing boards of the special hospitals for diseases of the chest in this country Admission to most of these can be obtained by subscribers' letters only, and whilst indeed the in patients are all suffering from some form of chest disease yet quite half the out-patients have nothing at all the matter with the respiratory organs and yet use the "letters' which might with much more advantage be given to patients who are the subjects of consumption or of some other chest trouble

Climates suitable for consumptives are next described and Dr Ransome's words are naturally quoted. "There are many places in this country where on a dry soil and in a sunny sheltered part on the southern slope of some upland most of the conditions can be obtained which are now dearly bought and far sought and often not obtained in distant parts of the world' No doubt these words are to a great extent true although we doubt whether in the civilised world there is a much more unsuitable climate than England as a whole, and certainly Dr. Walters's dictum that the locality for the sanatorium must have "*a pure air, free from* dust and smoke and the impurities which are inseparable from a dense population," would at once exclude the "hygienic treatment" being attempted in the strictest sense in a large town Several chapters are devoted to the description of the requirements of a sanatorium, the most suitable site (stress being laid on the fact that the coast is by no means always the best), the extent and nature of the sanatorium grounds, the construction, decoration, and furniture of the buildings, the cleansing and disinfection of the linen and rooms, the reception and disinfection of the sputa, the disposal of the sewage, and the water supply Next we find described the atmospheric conditions required for the fresh air treatment, such as natural and artificial shelter, protection against hot sun, and against wind, rain, and dust Directions are also given as to the regulation of rest and exercise, and a full description of the diet used in modern sanatoria follows Chapters then *follow* in which will be *found a discussion* on sanatoria for the poorer classes and the way in which they should be conducted Dr Walters enters into considerable detail as regards the size, staff, and management, and also answers some of the objections which have been raised against such institutions, referring chiefly to the danger of infection He barely touches, however, upon another greater difficulty—namely, as to how far it is advisable to increase the number of charitable institutions already in existence, the funds for the maintenance of which can only be secured with the greatest difficulty

The main part of the book is devoted to a description of the sanatoria in all parts of the world already existing or in course of construction The author has evidently spared no pains in collecting the information and a most valuable guide to such institutions is the result, probably the best that has hitherto been written The work is consequently a valuable one to all practitioners, as by referring to it details will be found of all such sanatoria wheresoever situated In addition to the written description numerous illustrations and plans of the various resorts are given The means of approach are also given so that the medical adviser can give to his patient all the necessary knowledge before the latter leaves England For this part of the book we have nothing but praise and can confidently recommend it to our readers In the last chapters of the book an appeal is made for the construction of sanatoria for the less wealthy middle class consumptives and it is shown by statistics how far Germany is beyond us in this respect If the institutions could be made self supporting we should certainly have nothing to say against them We fully sympathise with the difficulties which such patients experience in securing the necessary medical treatment The very rich and the very poor can obtain what is required, but the class of persons to whom Dr Walters refers are often placed in a most unfortunate position

Sir Richard Douglas Powell in the preface lays stress on the part which the doctor should play in the management of cases of consumption in his private practice 'The family medical adviser and the health resort physician need, perhaps, more closely to supervise and regulate the conditions of life as regards exercise, rest, and diet, which as a part of the general treatment of the case are as important as the administration of remedies for particular symptoms. ...... Medical officers of health in this country have yet to acquire authority to do much more to regulate the sanitation of their districts with regard to consumption; and it is, I believe, through this means, in conjunction with better instructed advice given more uniformly by family medical practitioners to their clients, that the public will best learn the sanitary requirements necessary for that further diminution of the prevalence and mortality of the disease which medical science has already done so much to lessen." These remarks we cordially endorse.

Twentieth Century Practice, an International Encyclopædia of Modern Medical Science. Edited by THOMAS L. STEDMAN, M.D. New York. In 20 volumes. Vol. XII.: Mental Diseases, Children, and Old Age. London: Sampson Low, Marston, and Co. 1897. Pp. iv.-849.

THE volume commences with Mental Diseases (p. 254) by Dr. G. Fielding Blandford. The keynote is struck in the words, "we must keep ever before us the fact that disorder of the mind means disorder of the brain and that the latter is an organ liable to disease and disturbance like other organs of the body, to be investigated by the same methods and subject to the same laws"—an excellent enough principle if steadily kept in view and consistently carried out in practice. The author's long experience in lunacy and his position as Lecturer in Psychological Medicine at St. George's Hospital give sufficient guarantee of fair performance in the task of writing the chapters on the Basis, Clinical Forms, Pathology and Medico-Legal Aspects and Treatment of Lunacy, though the necessary restrictions of space operate in a measure disadvantageously to a really adequate performance of the work. Stating that insanity is a wide and comprehensive term and mainly one of convenience, he advises the use rather of the term "the insanities" in speaking of the large and varied hosts of mental diseases, in conformity with what is doubtless increasing usage. The chapter on Cerebral Anatomy and Histology gives expression to the more recent results obtained, the *résumé* on Cerebral Histology and on the Comparative Evolution of the Brain—from the reptilian to the mammalian and human level—being mainly based on the work of Andriezen. The "insane diathesis" is briefly and well put, and concerning the insanities of puberty the author wisely says, "If we were to collect all the cases of insanity of puberty which are treated out of asylums and pass as cases of hysteria and the like we should greatly swell the number." The chapter on Homicide is practically excellent. It is unfortunate that "paranoia" is not accepted by the author, while "monomania" is retained as a term and has included under it not only *primary* cases but those *secondary* to antecedent (severe) attacks of mania, melancholia, &c., which is *rather inconsequent and confusing.* While some five monomanias—of pride, jealousy, hoarding, persecution, and doubt—are given there is no recognition of the clinical separateness and unity of Magnan's "délire chronique à évolution systématique"—a notable omission. As would be expected the subject of the Early Mental and Moral Changes of General Paralysis of the Insane—that most fatal of the insanities—is well described and its practical and medico-legal bearings are indicated. On the longevity of some insane patients the author has interesting remarks to make (p. 199). The chapter on the Prevention of Insanity is one of the best and should be perused by every practitioner and sociologist (the author had already given public utterances on this subject at the annual meeting of the British Medical Association at Bristol in 1895). A short and concise chapter on the Insane and the Law concludes what is on the whole an interesting and readable production.

Dr. Paul Sollier follows with a short monograph on Idiocy (110 pages). He accepts the classification of Bourneville—a pathological one—into eight varieties as, on the whole, the best—viz., into hydrocephalic, microcephalic, agenetic, malformative, hypertrophic-sclerotic, atrophic-sclerotic, meningetic, and myxœdematous (cretinoid). Then follow concise accounts of etiology (due stress being laid on alcoholism and on neurotic heredity as predominating ancestral conditions and causes of the disease); pathological appearances, mainly macroscopic; and the physical appearances and "stigmata"—the hebetudinous aspect, the conditions of the nose, ears, eyelids, palate and teeth (this part but meagrely), the jaws, and genital anomalies generally being briefly described. Sufficient data and statistics are not given, considering the importance of the subject. The author's forte is undoubtedly the psychology of the idiot mind, and he has given here in the compass of 60 pages what is undoubtedly an important contribution of real scientific value. A few pages are devoted finally to diagnosis, duration, and treatment, including the education and training of the idiot and the imbecile.

Professor Lombroso's contributions to criminology are already too well known to require any detailed description of his contribution on Criminal Anthropology (50 pages). This is mainly a *résumé* of more recent work (that of the past decade) initiated by Lombroso, Benedikt, and others, and carried out by a host of other workers. Lombroso recognises the following types or species of criminals: (*a*) the epileptic criminal; (*b*) the congenital; (*c*) the criminal by passion; (*d*) the accidental criminal—who, it need scarcely be said, is not of one blood with the first two types or with the next; and (*e*) the insane criminal. The accidental criminal, however, may from repetition become a chronic and habituated one. The geographical distribution of crime, and such topics as heredity, social abuses, and other conditions conducive to the development of crime are touched upon in Lombroso's well-known way. For a work of such small scope the statistical data are ample and even too abundant.

The psychology and pathology of old age have yet to be written. Dr. Boy-Teissier of Marseilles makes a praiseworthy attempt in this direction. He avails himself of the works of many predecessors—Cruveilhier and Charcot in France, Canstatt in Germany, and Day in England. The decay and failures of old age are morphologically considered as related to (1) pure atrophy of tissue elements of the body; (2) infiltration or degeneration—fatty, albuminous, calcareous—of organs; and (3) exaggerated production of connective tissue (arterio-capillary and other fibroses). Hygienic measures to preserve a "green old age unconscious of decay" are indicated. Some of the common ailments and troubles of old age are referred to, but the subject of psychological decadence is not adequately dealt with, this being the weakest part of the production.

The Diseases of Children by Dr. Comby of Paris conclude the volume. These refer to general nutritive disorders (exclusive of rickets, already dealt with in Volume II.) and local or regional diseases of the alimentary canal, respiratory organs, &c. The author recognises and delineates a scrofulous diathesis and an arthritic, including in this latter tendencies to such diseases as migraine, asthma, coryza, pharyngitis, &c., combined with an undue irritability of the child's nervous system. Dr. Comby certainly makes a good case for this classification. The concluding chapters relate to cutaneous affections of childhood, viz.—congenital anomalies (well described), the erythemas, affections of the sebaceous and sweat glands, pemphigus, the exfoliative, vesicular, and other dermatites, the keratoses, and affections due to vegetable (fungoid) and animal parasites of the skin. The nervous diseases of children are dealt with in what is on the whole a concise and useful summary and an excellent bibliography is appended. A general index of 17 pages concludes this work, the usefulness of which is apparent, though the various parts are of unequal merit.

An American Text-book of the Diseases of Children. Edited by LOUIS STARR, M.D., late Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania; assisted by THOMPSON S. WESTCOTT, Instructor in Diseases of Children, University of Pennsylvania. Second edition, revised, two vols. Numerous Illustrations and several Coloured Plates. London: Rebman Publishing Co., Limited. 1898. Pp. 1230. Price 42*s.*

THE fact that this encyclopædic work has already reached its second edition shows that its many excellent points have been appreciated by the medical public. As we pointed out in reviewing the first edition the book is very unequal in quality. Most of the articles are written with undoubted authority by those who have special experience, but in some the various forms of disease are described as they occur in the adult, thus covering ground which has been better dealt with elsewhere. Again, while syringomyelia and other affections rarely presenting themselves for observation during childhood are described in detail there are diseases met with in characteristic forms in early life, such as the osteo-arthritis of children, which have been omitted altogether. But with this not unimportant reservation we can heartily recommend the book, many of the articles being of the first order, particularly that by the Editor on the Clinical Examination and Management of Sick Children, that on Modified Milk by Dr. Westcott, that on Tuberculosis by Dr. Osler, those on Tuberculous Meningitis and other Nervous Diseases by Dr. Hendrie Lloyd, and the admirable practical sections on Tracheotomy and Intubation by Dr. Henry Wharton. The index is very complete, and the book is well printed and strongly bound.

LIBRARY TABLE.

The Century Invalid Cookery Book. By MARY A. BOLAND Edited by Mrs. HUMPHREY. London: T. Fisher Unwin. 1898. Price 3*s.* 6*d.*—It must be acknowledged that for invalids in particular good cookery is of the greatest importance since all food as nourishment to repair the waste of the tissues of the body may be spoiled by improper cooking. Further, bad cooking may also render otherwise good food unattractive to the invalid. To win the interest of her readers the author of this book devotes the first part of it to explanatory lessons which include general remarks upon chemical composition, applying this information to practical purpose. A full knowledge of the processes and changes in the composition of food by heat emphasises the necessity for careful attention in its preparation. The perfection of cooking is reached when the nourishment in the food is thereby made most easily available by the digestive processes. Too much stress can hardly be laid upon the want of pure air as an adjunct to good food and as an essential of health, a point which is well emphasised. The second part consists mainly of recipes which are clearly written and which should easily be followed by novices in the culinary art. Suggestions for the tasty serving of food and a chapter devoted to the feeding of children with directions for the sterilisation and preservation of milk are valuable additions to the book. It is written principally for the use of nurses and all who tend the sick, but it should be useful to a larger class and in fact to all those who would possess a knowledge of the principles underlying the advantages of well-chosen and well-cooked food. Air and food-supply are responsible for the maintenance of strength and both factors are especially indicated under the best possible conditions for those who hope to overcome the weakness following disease. The elementary scientific facts are correctly stated, but there is a curious mixture of nomenclature in the book; sometimes it is American and sometimes English. Frequently, again, the word "symbol" is used when "formula" is meant.

Merck's Digest. London Office, 16, Jewry-street.—We have received the first number of this periodical which is devoted to the publication of reports on clinical experiments made with the preparations elaborated by this enterprising firm. The present number deals with the glycerino-phosphates and contains the chemistry of this interesting series of nerve nutrients and stimulants with clinical results. The periodical will be forwarded to medical men gratis on application.

JOURNALS.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S. New Series, No. 164, Vol. XLI., Part 4. January, 1899. London: J. & A. Churchill. Price 10*s.*—This part contains the following articles. 1. On Differences in the Histological Structure of Teeth occurring within a Single Family, the Gadidæ, by Charles S. Tomes, M.A., F.R.S. Mr. Tomes shows that true dentinal tubes are not found in this very well-marked and natural group of fishes, but that they present typical vaso-dentine, which consists of a matrix permeated by a rich plexus of blood-carrying channels. These channels proceed from large axial pulp cavities. In merlucius, molva, brosmius, lota, and probably uraleptus, the vascular canals are highly developed, the outer non-vascular portion being sharply marked off by the bounding canal. In raniceps gadus and motella the vascular canals, abundant in gadus morrhua, become less frequent in the other species but always retain rounded external loops; in phycis, perhaps in uraleptus and lotella, the vascular loops are greatly reduced in number, and, indeed, in lotella they are entirely absent. Incidentally, Mr. Tomes thinks that his observations tell against the doctrine of kinetogenesis, which is to the effect that the form of a tooth is the direct consequence of the direction of stimulation which it has received by use in successive generations, for he finds that the gillrakers of the hake which are subject to the minimum of use are an exact copy of the teeth round the margins of the mouth. 2. A Description of Two New Species of Spongilla from Lake Tanganyika, by Richard Evans, B.A. These sponges were collected by Mr. J. E. S. Moore, and were taken from a depth of 350 fathoms. The sponges examined, named respectively Spongilla Moorei and Spongilla Tanganyika, grow on shells, are lobulated and somewhat woolly in aspect, an *osculum* of about one-eighth of an inch in diameter is situated at the tip of each of the lobes, and the dermal pores are small and are situated on the flanks of the lobes and on the intermediate depressions. Some of the spicules are diactinal monaxons, tapering to a sharp point at the two ends and without swellings on the shaft, others are similarly formed but have swellings, and others are formed by the fusion of these forms. The general arrangement of the skeleton is reticulate. All the skeletal fibres of the Spongilla Moorei are enclosed in a distinct sheath of spongin. The gemmules are spherical and small. In the Spongilla Tanganyika the spicula present megascleres and microscleres and these are thickly covered with small spines. The spongin is not so highly developed as in the Spongilla Moorei. It presents a certain degree of affinity with the species of the Spongillinæ on the one hand and of the Lubomirskinæ on the other. 3. On Tetracotyle Petromyzontis, a Parasite of the Brain of Ammocœtes, by Albert W. Brown, B.A. Careful examination of this remarkable specimen demonstrated that it was a holostomid trematode. It presents a remarkable similarity in appearance to the diplostomum volveus. It appears to be almost constantly present in the brain cavities of Ammocœtes, as Mr. Brown only noted its absence in one case after examining many. The parasites are found mostly in the region of the fourth ventricle and have not been observed by Mr. Brown in the adult lamprey. He thinks that they may reach the brain through the blood-vessels, but their position is difficult to explain. Their presence does not seem to incommode their host. Mr. Brown gives drawings of the animal and of the structure of its parts. 4. Studies on the Structure and Formation of the Calcareous Skeleton of the Anthozoa, by Gilbert C. Bourne, M.A., with four plates. This paper is to a considerable extent a criticism of Mr. Gordon's views on the mode of formation of madreporia. 5. The Structure and Development of the Hairs of Monotremes and Marsupials, by Baldwin Spencer, M.A., Professor of Biology in the University of Melbourne, and Georgina Sweet, M.Sc., of Melbourne University, with three plates. The hairs of these groups, it appears, are arranged in bundles with a common follicular neck, the number of hairs thus collected into one group varying from four or five to 30. The shaft is always round a bundle of muscular fibres (unstriated in ornithorrhynchus but striated in echidna) is connected with each group of hairs. The authors describe eight stages of development from the first appearance of a solid downgrowth of the epidermis to the emergence of the hair. The lumen is found at quite a late period. There is no real distinction of the inner root sheath into Huxley's and Henle's layers. The development of the hairs is essentially similar to that of other mammals. The paper is illustrated by numerous well-executed drawings. 6. Trophoblast and Serosa, a contribution to the Morphology of the Embryonic Membranes of Insects, by Arthur Willey, D.Sc. Lond. In this article the author endeavours to trace the serosa back to a primitive trophoblast and the amniotic cavity back to a primitive ventral flexure.

Annales de Gynécologie et d'Obstétrique. January, 1899. Paris: G. Steinheil.—This number contains the following papers. On the Indications for the Induction of Abortion, by Professor Pinard, in which the conclusions arrived at are that neither cases of contraction of the pelvis nor cases of disease complicating pregnancy are indications for this operation and that the only real indication at the present day is when the cause of the danger menacing the mother's life is certainly the pregnancy. The Treatment of Chronic Metritis by Injection of Chloride of Zinc, by Dr. Pierre Delbet. On the Slowing of the Pulse during the Puerperium, by Dr. H. Varnier. On Vaginal Hysteropexy, by Professor Dührssen. Anomalies of the Genital Organs, by Dr. P. Delagénière. The number also includes a review of Russian medical periodicals and the usual quarterly bibliographical index.

Annales de l'Institut Pasteur. Tome xiii. No. 1, January, 1899. Paris: Masson et Cie.—This number contains the following articles: (1) Récherches expérimentales sur les Maladies des Plantes, by M. *Emile Laurent*; (2) Etude sur l'Immunité vis-à-vis des Composés Arsenicaux, by Dr. Beschredka; (3) Action du B. Coli et du Bacille d'Eberth sur les Nitrates, by M. L. Grimbert; (4) A Critical Review by the Editor (M. Duclaux) of a paper by Schottelius "On the Important Rôle Played in the Intestine by Bacteria." Of these the most important is that by M. Laurent on bacterial diseases among plants, giving a fascinating account of researches which not only promise to be of great value to the agriculturist but which have a most important bearing on the occurrence of diseases in epidemic form. The paper is too long to be quoted at length, but it may be mentioned that a piece of ground was taken and divided into plots, each of which was treated with a different manure. M. Laurent found that while healthy living potatoes resisted the bacterium coli those grown in soil containing an excess of chalk had their resistance weakened, so that colonies readily formed on cut surfaces of the potato while those grown in a soil without an excess of alkali continued to resist. Further, he found that by growing on this feebly-resisting potato the virulence of the organism was greatly increased, so that after being once cultivated on the potato it would at once attack the stronger tubers when inoculated and thus might give rise to an epidemic. With other organisms the tubers grown in the alkaline soil resisted best and the addition of chalk to the soil would lead to the arrest of the spread of disease from one potato to another in the same patch. In connexion with some half-dozen well-known organisms which attack higher plants it was found that modifications of the soil would so alter the resisting power of the plants that they escaped infection or recovered if infected. It seems probable that further study of "vegetable therapeutics" on these lines may give some important hints which will aid the physician in controlling disease in man.

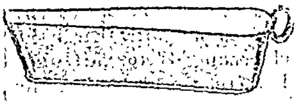
Public Health.—This, the journal of the Incorporated Society of Medical Officers of Health, contains in its February number some interesting papers. First, there is Dr. Newsholme's paper upon the Prevention of Phthisis, an abstract of which appeared in our issue of Feb. 4th. Then there is an article by Dr. John Robinson upon Slop Closets which he considers should not be used in crowded towns. Dr. William Butler publishes a paper, originally read before the Home Counties Branch of the Incorporated Society of Medical Officers of Health, upon the Value from a Public Health Standpoint of the Declining Phthisical Death-rate. Dr. Butler concludes that it is not of much service to the community to reduce the death-rate from phthisis unless some restrictions are put upon the procreation of the degenerate. He says, "A healthy people pruned of its decadents by a high mortality among its children is better than a degenerate race weakened by the survival of its effete progeny."

New Inventions.

ASEPTIC CATHETER TRAY.

THE accompanying illustration represents a tray which has been thoroughly well made in white enamelled metal at my suggestion by Messrs. Reynolds and Branson, Limited, of Leeds. The original design was carried out for me some 12 years ago by a local tinsmith.

The trays are 10½ inches long by three inches deep and are three and a half inches wide behind but taper to two and a half inches in front. They are furnished with a handle and being coated with white enamel are easily sterilised by boiling. Placed between the thighs with the narrow end pressed against the perineum they will be found most useful when drawing off urine in either sex or while washing out the bladder; during the radical treatment of hernia, varicocele, or hydrocele, and during operations on the lower abdomen they will prevent fluids getting down between the thighs. They are also suitable for operations on the breast or for empyema, the narrow end being pushed up into the axilla.



REGINALD H. LUCY, M.B. Edin., F.R.C.S. Eng.,
Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

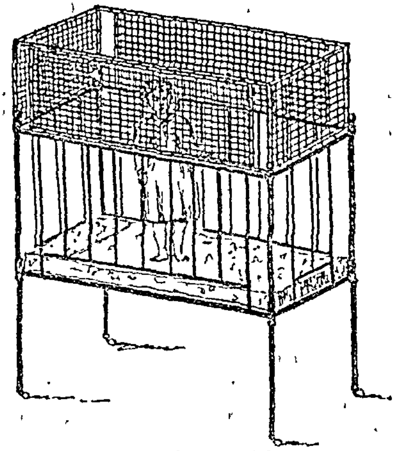
A NEW SYPHON-HEAD.

A VERY desirable improvement has been effected in the construction of the syphon head of aerated water-bottles by Messrs. Ellis and Son of Ruthin. It enables the charging of the bottle without removing the head while it allows of absolute cleansing of all the parts as well as of the bottle itself.

The spring valve, instead of being vertical, is horizontal, the spout being much in the same position as in the ordinary design. The valve in reality forms a sort of T piece, the handle being at one end while at the other is a screw-piece which may be easily detached either for charging or cleansing. For the former purpose the head is simply screwed on to the charging apparatus, but if during charging the valve be depressed water will be rapidly forced through the bottle and spout. This arrangement, further, adds to the convenience of using the syphon. The improvement is an important one since its adoption guarantees freedom from dirt and other impurities in the water contained in the syphon.

THE "HAPPY THOUGHT" COT PROTECTOR.

To prevent falls from the cot which are a frequent cause of injury to children just beginning to walk and to climb about is the object of an invention by one of my patients. It consists of a light frame of bamboo and netting which can be easily fixed to the cot and removed at pleasure. The child is thus prevented from falling out of bed, and can play about freely if awake and restless while the mother or nurse is still asleep The frame can be folded up into a small space when not required. I am informed that the frame costs from 12*s*. 9*d*. to 14*s*. 9*d*. and that it may be obtained from Messrs. Maple and Co. and Messrs. Shoolbred and Co. in London, Messrs. Pim Brothers in Dublin, and others of the chief furniture makers.



Clifton. GEORGE PARKER, M.D. Cantab.

THE VALLEY OF THE THAMES AND THE THAMES CONSERVANCY BOARD.

ON Feb. 13th a deputation, introduced by Viscount Valentia, M.P., and consisting of representatives of district councils in the counties of Berkshire, Buckinghamshire, Hertfordshire, Gloucestershire, Oxfordshire, Surrey, and Wiltshire, was received at the offices of the Thames Conservancy by Sir F. Dixon-Hartland, M.P., the Chairman, and by several other members of the Thames Conservancy Board.

Viscount **Valentia** said that the representative gentlemen whom he introduced were fully impressed with the great importance of preserving the Thames from contamination, but they thought that pollution of minor streams in their particular districts was not likely to affect the purity of the river because in their opinion water became purified by a natural process of filtration on its way to the Thames. They knew that the Thames Conservancy Board under the Act of 1894 had most stringent powers, but they feared that if these were enforced to the letter unnecessary expense would be caused in the districts which they represented.

Mr. **White**, Chairman of the Headington Rural District Council, said that the council which he represented had received notices with regard to streams three or four miles from the Thames from which he thought no possible pollution could be caused to the river. He complained that a field ditch which carried only the washings of a road was condemned and it led to a summons being issued against the Headington Rural District Council, and he suggested that this was unfair because at Magdalen Bridge at Oxford, near the Botanical Garden, a drain still discharged into the river.

Mr. **Harry Bevis**, clerk to the Cricklade Wootton Bassett Rural District Council, pleaded that the Conservators should exercise their powers in a lenient and broad spirit. He thought that the creation of a number of sewage farms along the Thames would be more prejudicial to the river than the present arrangements.

Sir F. **Dixon-Hartland**, M.P., in reply, began by pointing out that Lord Derby in reply to a criticism with regard to the barrenness of the session of 1866 had said that if they had secured, as he believed they had, the purification of their great national river their labours would not have been in vain. The Act of 1866 had been amplified and extended by the Acts of 1870, 1878, and 1894. The last Act, which was passed after a laborious report made by a Parliamentary Committee, left the Thames Conservators no option with regard to the duties which they had to perform. They had under their supervision no less than 100 district councils. Since the year 1896 only 18 convictions had taken place. Of these six occurred in the counties of Hertfordshire, Berkshire, and Buckinghamshire, and 12 in Surrey, Hampshire, and Middlesex. In addition to these cases 15 summonses had been issued, of which 10 had been adjourned and five withdrawn. During this period 10 convictions against private individuals had also been obtained. The fact that so little litigation had taken place showed that the Conservators had acted with great forbearance. Their duty was to see that neither the river nor its effluents were polluted. The Conservators had never insisted on any particular system of sewage. They had always allowed districts to decide for themselves what system it was best to carry out and local authorities had complete liberty of action in that respect. The members of the deputation should also bear in mind that in all cases the convictions which had been made were by local magistrates and that no conviction could possibly take place unless there were a real breach of the law. With regard to the delegates who had addressed the Conservators the Chairman pointed out that in the case of Oxford the sewage effluent farm had gradually improved and as soon as they had discovered pollution to exist in the city they had immediately taken steps to stop it. Headington, from which a member of the deputation had come, was one of the worst offenders. It was, indeed, the only place on the Thames where nothing whatever had been done to carry out the requirements of the Conservators. They had been most patient and had finally adjourned an imminent prosecution to March 4th next in order to give them a last chance. Reports with regard to the sewage effluents at Headington had been uniformly bad. It had been suggested that the Conservators should give a few days' notice of the time at which their inspector would visit rural districts They had no objection to giving notice on the morning of the day on which their representative made his visit, but the Conservators did not think it wise to give a few days' notice in order that preparations might be made for his reception. The Chairman said that he had been very glad to see the deputation. Some years ago they had received one which was introduced by the Earl of Jersey and the members of that deputation, he believed, had returned satisfied with their interview with the Conservators. He was glad to say that since the year 1894 the purity of the Thames was improved by one-third. In no less than 362 places pollutions had been diverted. The district over which they had sway contained a population of 500,000 people, the work which they had to carry out was of the greatest importance, their duties were strictly laid down, and they had always been as considerate as they could having regard to their responsibilities.

At the conclusion of Sir F. Dixon-Hartland's speech Lord **Valentia** thanked the Chairman and the Board for granting the interview.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 18, 1899.

THE Parliamentary Bills Committee of the British Medical Association has had under its consideration a Midwives Bill sent up by the Medical Acts Amendment Sub-committee. The Sub-committee had taken the Bill of the Midwives Institute, as amended to meet the views of the General Medical Council, as a basis of discussion and had subjected it to a pretty close criticism. The report of the Sub committee accepted the fact that some such Bill is likely sooner or later to be passed by Parliament and suggested such amendments in it as would still further tend to secure the objects which the General Medical Council had in view, and must keep in view, in consenting reluctantly to any legislation of this kind. There was, indeed, an attempt by Mr. GEORGE BROWN, notwithstanding his general assent to the views of the Council, to throw the whole thing overboard, as will be seen by the amendment which he proposed to the motion of Dr. WOODCOCK. Dr. WOODCOCK's motion, which was seconded by Mr. HORSLEY, was as follows:—

"That the Bill thus amended be adopted and referred to the Council for adoption as that form of legislation on this subject which alone includes adequate safeguards both for public health and for the interests of the medical profession."

Mr. BROWN's amendment was—

"That inasmuch as the great majority of general practitioners have repeatedly objected to the registration of midwives this committee recommend the Council to oppose the Bill."

Dr. WOODCOCK's motion was carried. There is a sense, of course, in which the whole profession is reluctant to agree to such legislation. It is pitiable to think that any woman in the dangers of childbirth should have any attendant who does not act with the full knowledge and sense of responsibility of a qualified and registered medical practitioner. But taking the world as it is, and is likely to be for many years to come, we cannot shut our eyes to the fact that in this country a large proportion of the wives of the poorer classes are attended in their confinements by an untaught, untrained, and unregulated class of midwives whose practice the State has not prohibited, and has no intention of prohibiting, save perhaps in the sense of regulating it and subordinating it to the supervision of the medical profession. Such restraint will be imposed by a Midwives Bill, if passed by Parliament, in full accordance with the principles laid down by the General Medical Council and amplified in the Bill adopted by the Parliamentary Bills Committee of the British Medical Association.

The amendments to the Midwives Bill of the Midwives Institute which have been suggested by the Medical Acts Amendment Sub-committee are numerous. Some of them will appear to the framers of the Midwives Bill to be superfluous and to aim at provisions already involved, if not expressed, in one or other of the sections of the Bill. They are well set forth, as are the reasons for them, in the temperate and able speech of Dr. WOODCOCK. The Sub-committee wished to make clear in almost the first clause of the Bill the essentially subordinate and limited function of the midwife by defining her as "a woman who undertakes for gain to attend cases of women during natural labour and the lying-in period under the rules, regulations, and medical control or supervision set forth in this Act." We approve of this fuller definition of the new midwife in the front of the Bill. There is a very proper clause forbidding the employment of any substitute who is not licensed. The clauses of the Bill of the Parliamentary Bills Committee denying all medical function to the midwife and all right to give medical certificates also specifically forbids her, under penalty of fine or imprisonment, to give a certificate of still birth. Objections to such a clause being inserted in a Bill not dealing directly with the registration of births and deaths have been raised but they are pedantic: clearly the opportunity of such a Bill as the present should be seized to stop a great evil and danger. The Sub-committee did not approve of the recognition of the certificate of the Obstetrical Society of London. They considered that it would be better to leave the matter entirely to the Midwives Board. Perhaps the most novel feature of the Bill is that dealing with the constitution of the Midwives Board. The Board is commendably smaller than in the previous Bill of the Parliamentary Bills Committee. It is to consist of only seven members—all registered medical practitioners. One is to be appointed by the Lord President of the Privy Council, the remaining six, not by the medical corporation and the Institute of Midwives, as in the Bill of the latter body, but by the General Medical Council. Moreover, they are to be resident or practising in the different divisions of England and Wales that they may the better represent localities. Under section 6 of the Bill, sub-section 6 provides that no member of the Board shall act as teacher, instructor, or examiner of midwives, and that no member of the Board shall take any part in any inquiry respecting the conduct of any midwife to whom he or she has acted as a teacher or instructor. The latter part of this sub-section seems not unreasonable, but the exclusion of every teacher of midwives from the Board might deprive the Board of some very useful help.

Other provisions are good—viz., one giving the duties of local supervision to a committee of not less than three practitioners, to be elected by the administrative county council; one making it an offence for a midwife to fail to send for a medical man in any case which is not one of natural labour; and one requiring premises in which lying-in women are received by midwives to be subject to regulation and inspection under rules to be laid down by the Midwives Board and approved by the General Medical Council. The Parliamentary Bills Committee seems to think that the existing Midwives Bill gives no power to the Midwives Board to lay down rules and regulations for the training and education of midwives Surely this power is given in section 5 and its various sub-sections However, there can be no harm in making the point more definite On the whole it will be seen that we approve the alterations or amendments of the Parliamentary Bills Committee But the question is not yet solved

---

A BITTER cry goes up from all the interests—and they are numerous—which in Southern Europe, and especially on the Mediterranean, subsist upon the English speaking sojourner The first note in the lugubrious concert was struck by France who has been heavily hit by the abstention of her British American *clientele* Not only in Paris, but more particularly on the Riviera the hotels, the restaurants, the cafés, the theatres, the public vehicles, the great shops, have not done half their usual business, while, according to a leading Parisian journal, the Mont-de Piété has trebled or quadrupled its operations, the pledges being mainly in jewellery or in objects of artistic value—a sure sign that the prevailing impecuniosity has touched the higher social grades Every kind of explanation is sought for this falling off or failure of the "foreign import ' The Americans give France a wide berth "because of her pronounced sympathies with Spain in the late war , the English go elsewhere "on account of the policy of pin pricks and of "possible hostilities' Another reason is found in the "husbanding of resources for the great Exposition of 1900! ' And so on in similar strain, till the conclusion is forced upon the reflecting mind that English speaking custom is so essential a factor in French prosperity that war between the two nations is impossible But if France is loud in her lamentations over the abstention of the foreigner, Italy is louder still, making her voice heard, moreover, not through her journals only, but in her municipal councils and in Parliament itself From San Remo to Palermo, from Venice to Taormina, the "missing Inglese ' is felt as little short of a national calamity—the "absent visitor' being tantamount to a "present visitation Let us illustrate by a concrete example what this arrest of an annual source of revenue means for Italians Some years ago in Florence there was a fever scare, the dismantling of the "Centro having led to the overcrowding of the San Frediano quarter with the inevitable result In dread of the epidemic, the English speaking world left "our Lady of Flowers severely alone till the *custode* of her chief picture gallery had to inform his principal that for January, February, and March his sale of one franc admission tickets had been 16,000 fr less than during the corresponding three months of the previous year—in other words, that in that particular winter there had been 16 000 fewer visitors than in the winter of the twelve month before This season it is no fever scare that keeps the British American away from Italy The same causes which explain his abstention from the French Riviera—dread of war, for instance—may, to some extent, account for his abstention from the Italian But there are other reasons of a more permanent kind which underlie the phenomenon and it is well that Italy for her own sake should ponder them seriously, take to heart the lesson they teach, and rehabilitate herself accordingly

In "climatic therapeutics,' as in "medical meteorology," there are ever new developments inviting ever new departures The Mediterranean littoral is giving place to health-resorts farther south and farther east Egypt and the Nile are proving fatal to Riviera Ponente and Riviera Levante alike, and if these latter are to keep "in the running ' they must "improve their condition ' in every possible way Italy, as we have said, is undergoing much heart-searching on the subject and an article in the *Nuova Antologia* by a distinguished member of her Parliament has endeavoured to "take stock of the situation" and to suggest reforms in her traditional modes of dealing with her "paying guests" The article, widely quoted and annotated by the Italian press, does certainly indicate many shortcomings and actual abuses in the treatment which she vouchsafes to the visitor who, except perhaps in the great cities or in the line of tourist traffic, is seldom allowed to forget that he is virtually in a mediæval country But it really touches little more than the fringe of the problem, "how to attract the *forestiere* " It leaves out what is paramount and essential — the safety of the *forestiere* aforesaid not only from custom house vexations, and hotel exactions, and mendicant importunities, and "shadowings ' by touts, and luggage robberies, and brigandage itself, but from imperfect hygiene in drainage in water supply, in food and drink and in sanitary requirements generally, to say nothing of the crusade renewed session by session in Parliament for replacing the English speaking practitioner by an Italian whose linguistic acquirements seldom include more than a little bad French and whose practice—at least outside the greater medical schools—is not such as to command British American partialities

From time to time THE LANCET has been at special pains to show Italy how she might not only attract the *forestiere* but keep him as a yearly returning, if not perennial, guest, and a few years ago we published a series of articles[1] putting in evidence the substantial—in some respects the unique—recommendations of the North Sicilian littoral as a health resort, particularly at its chief town, Palermo May we invite our Italian brethren, now that the question of attracting the English speaking world is agitating the kingdom, to re peruse and re consider those articles and to take to heart or give practical effect to the large and liberal policy which they indicate? Not only are there other places calling out for adequate development, hygienically and professionally, not less imperiously than Palermo, but even in the traditional and well-established resorts there is much still to be done to bring them level with British American desiderata and to justify the English speaking practitioner in recommending them Take the capital itself How often has a convalescent, from malaria for instance, who has sighed for a change to purer air and fresher surroundings attainable within an hour or two of the scene of his sufferings been told that to get what he wants he must risk a tedious railway journey of over half a day? And yet little more than 10 miles from the Porta San Giovanni there are the Alban Hills and the so called Hannibal s Camp—a mountain-plateau about 3000 ft above sea level, sheltered from

THE LANCET.

LONDON: SATURDAY, FEBRUARY 18, 1899.

THE Parliamentary Bills Committee of the British Medical Association has had under its consideration a Midwives Bill sent up by the Medical Acts Amendment Sub-committee. The Sub-committee had taken the Bill of the Midwives Institute, as amended to meet the views of the General Medical Council, as a basis of discussion and had subjected it to a pretty close criticism. The report of the Sub-committee accepted the fact that some such Bill is likely sooner or later to be passed by Parliament, and suggested such amendments in it as would still further tend to secure the objects which the General Medical Council had in view, and must keep in view, in consenting reluctantly to any legislation of this kind. There was, indeed, an attempt by Mr. GEORGE BROWN, notwithstanding his general assent to the views of the Council, to throw the whole thing overboard, as will be seen by the amendment which he proposed to the motion of Dr. WOODCOCK. Dr. WOODCOCK'S motion, which was seconded by Mr. HORSLEY, was as follows:—

> "That the Bill thus amended be adopted and referred to the Council for adoption as that form of legislation on this subject which alone includes adequate safeguards both for public health and for the interests of the medical profession."

Mr. BROWN'S amendment was—

> "That inasmuch as the great majority of general practitioners have repeatedly objected to the registration of midwives this committee recommend the Council to oppose the Bill."

Dr. WOODCOCK'S motion was carried. There is a sense, of course, in which the whole profession is reluctant to agree to such legislation. It is pitiable to think that any woman in the dangers of childbirth should have any attendant who does not act with the full knowledge and sense of responsibility of a qualified and registered medical practitioner. But taking the world as it is, and is likely to be for many years to come, we *cannot* shut our eyes to the fact that in this country a large proportion of the wives of the poorer classes are attended in their confinements by an untaught, untrained, and unregulated class of midwives whose practice the State has not prohibited, and has no intention of prohibiting, save perhaps in the sense of regulating it and subordinating it to the supervision of the medical profession. Such restraint will be imposed by a Midwives Bill, if passed by Parliament, in full accordance with the principles laid down by the General Medical Council and amplified in the Bill adopted by the Parliamentary Bills Committee of the British Medical Association.

The amendments to the Midwives Bill of the Midwives Institute which have been suggested by the Medical Acts Amendment Sub-committee are numerous. Some of them will appear to the framers of the Midwives Bill to be superfluous and to aim at provisions already involved, if not expressed, in one or other of the sections of the Bill. They are well set forth, as are the reasons for them, in the temperate and able speech of Dr. WOODCOCK. The Sub-committee wished to make clear in almost the first clause of the Bill the essentially subordinate and limited function of the midwife by defining her as "a woman who undertakes for gain to attend cases of women during natural labour and the *lying-in* period under the rules, regulations, and medical control or supervision set forth in this Act." We approve of this fuller definition of the new midwife in the front of the Bill. There is a very proper clause forbidding the employment of any substitute who is not licensed. The clauses of the Bill of the Parliamentary Bills Committee denying all medical function to the midwife and all right to give medical certificates also specifically forbids her, under penalty of fine or imprisonment, to give a certificate of still birth. Objections to such a clause being inserted in a Bill not dealing directly with the registration of births and deaths have been raised but they are pedantic: clearly the opportunity of such a Bill as the present should be seized to stop a great evil and danger. The Sub-committee did not approve of the recognition of the certificate of the Obstetrical Society of London. They considered that it would be better to leave the matter entirely to the Midwives Board. Perhaps the most novel feature of the Bill is that dealing with the constitution of the Midwives Board. The Board is commendably smaller than in the previous *Bill* of the Parliamentary Bills Committee. It is to consist of only seven members—all registered medical practitioners. One is to be appointed by the Lord President of the Privy Council, the remaining six, not by the medical corporation and the Institute of Midwives, as in the Bill of the latter body, but by the General Medical Council. Moreover, they are to be *resident or practising* in the different divisions of England and Wales that they may the better represent localities. Under section 6 of the Bill, sub-section 6 provides that no member of the Board shall act as teacher, instructor, or examiner of midwives, and that no member of the Board shall take any part in any inquiry respecting the conduct of any midwife to whom he or she has acted as a teacher or instructor. The latter part of this sub-section seems not unreasonable, but the exclusion of every teacher of midwives from the Board might deprive the Board of some very useful help.

Other provisions are good—viz., one giving the duties of local supervision to a committee of not less than three practitioners, to be elected by the administrative county council; one making it an offence for a midwife to fail to send for a medical man in any case which is not one of natural labour; and one requiring premises in which lying-in women are received by midwives to be subject to regulation and inspection under rules to be laid down by the Midwives Board and approved by the General Medical Council. The Parliamentary Bills Committee seems to think that the existing Midwives Bill gives no power to the Midwives Board to lay down rules and regulations for the training and education of midwives. Surely this power is given in section 5 and its various sub-sections However, there can be no harm in making the point more definite On the whole, it will be seen that we approve the alterations or amendments of the Parliamentary Bills Committee. But the question is not yet solved

A BITTER cry goes up from all the interests—and they are numerous—which in Southern Europe, and especially on the Mediterranean, subsist upon the English speaking sojourner. The first note in the lugubrious concert was struck by France who has been heavily hit by the abstention of her British-American *clientèle* Not only in Paris, but more particularly on the Riviera, the hotels, the restaurants, the cafés, the theatres, the public vehicles, the great shops, have not done half their usual business, while, according to a leading Parisian journal, the Mont de Piété has trebled or quadrupled its operations, the pledges being mainly in jewellery or in objects of artistic value—a sure sign that the prevailing impecuniosity has touched the higher social grades Every kind of explanation is sought for this falling off or failure of the "foreign import" The Americans give France a wide berth "because of her pronounced sympathies with Spain in the late war", the English go elsewhere "on account of the policy of pin-pricks" and of "possible hostilities" Another reason is found in the "husbanding of resources for the great Exposition of 1900!" And so on in similar strain, till the conclusion is forced upon the reflecting mind that English-speaking custom is so essential a factor in French prosperity that war between the two nations is impossible But if France is loud in her lamentations over the abstention of the foreigner, Italy is louder still, making her voice heard, moreover, not through her journals only, but in her municipal councils and in Parliament itself. From San Remo to Palermo, from Venice to Taormina, the "missing Inglese" is felt as little short of a national calamity—the "absent visitor" being tantamount to a "present visitation" Let us illustrate by a concrete example what this arrest of an annual source of revenue means for Italians Some years ago in Florence there was a fever scare, the dismantling of the "Centro" having led to the overcrowding of the San Frediano quarter with the inevitable result In dread of the epidemic, the English speaking world left "our Lady of Flowers" severely alone till the *custode* of her chief picture gallery had to inform his principal that for January, February, and March his sale of one franc admission tickets had been 16,000 fr less than during the corresponding three months of the previous year—in other words, that in that particular winter there had been 16,000 fewer visitors than in the winter of the twelve month before This season it is no fever scare that keeps the British American away from Italy The same causes which explain his abstention from the French Riviera—dread of war, for instance—may, to some extent, account for his abstention from the Italian But there are other reasons of a more permanent kind which underlie the phenomenon and it is well that Italy for her own sake should ponder them seriously, take to heart the lesson they teach, and rehabilitate herself accordingly.

In "climatic therapeutics," as in "medical meteorology," there are ever new developments inviting ever new departures The Mediterranean littoral is giving place to health-resorts farther south and farther east Egypt and the Nile are proving fatal to Riviera Ponente and Riviera Levante alike, and if these latter are to keep "in the running" they must "improve their condition" in every possible way. Italy, as we have said, is undergoing much heart-searching on the subject and an article in the *Nuova Antologia* by a distinguished member of her Parliament has endeavoured to "take stock of the situation" and to suggest reforms in her traditional modes of dealing with her "paying guests" The article, widely quoted and annotated by the Italian press, does certainly indicate many shortcomings and actual abuses in the treatment which she vouchsafes to the visitor who, except perhaps in the great cities or in the line of tourist traffic, is seldom allowed to forget that he is virtually in a mediæval country But it really touches little more than the fringe of the problem, "how to attract the *forestiere*." It leaves out what is paramount and essential—the safety of the *forestiere* aforesaid not only from custom-house vexations, and hotel exactions, and mendicant importunities, and "shadowings" by touts, and luggage robberies, and brigandage itself, but from imperfect hygiene in drainage, in water supply, in food and drink, and in sanitary requirements generally, to say nothing of the crusade renewed session by session in Parliament for replacing the English speaking practitioner by an Italian whose linguistic acquirements seldom include more than a little bad French and whose practice—at least outside the greater medical schools—is not such as to command British-American partialities

From time to time THE LANCET has been at special pains to show Italy how she might not only attract the *forestiere* but keep him as a yearly returning, if not perennial, guest, and a few years ago we published a series of articles[1] putting in evidence the substantial—in some respects the unique—recommendations of the North Sicilian littoral as a health resort, particularly at its chief town, Palermo May we invite our Italian brethren, now that the question of attracting the English speaking world is agitating the kingdom, to re peruse and re consider those articles and to take to heart or give practical effect to the large and liberal policy which they indicate? Not only are there other places calling out for adequate development, hygienically and professionally, not less imperiously than Palermo, but even in the traditional and well-established resorts there is much still to be done to bring them level with British-American desiderata and to justify the English speaking practitioner in recommending them Take the capital itself. How often has a convalescent, from malaria for instance, who has sighed for a change to purer air and fresher surroundings attainable within an hour or two of the scene of his sufferings been told that to get what he wants he must risk a tedious railway journey of over half a day? And yet little more than 10 miles from the Porta San Giovanni there are the Alban Hills and the so-called Hannibal's Camp—a mountain-plateau about 3000 ft above sea level, sheltered from all trying winds and combining hill-air and sea-breeze from the neighbouring Latin shore with a quietude, a local charm, and an historical impressiveness at once restorative and soothing—in every way welcome to invalid languor. But to get there he must undertake a journey half by rail and half by carriage on roads detestably bad; at his journey's end there is no well-appointed, well-served, well-managed hotel to receive him; and he has to fall back on the mediæval accommodation and semi-savage fare open to him at the "eagle's nest" of Rocca di Papa. Examples like these of opportunities neglected or of chances let slip by contemporary enterprise are simply innumerable and place in a rather hopeless light the misgivings of Italians as to the recovery of that "foreign element" upon which their country so depends—misgivings which lead to no organised reform or even attempt at self-rehabilitation. We hear from Naples, for example, that "non si reca nemmeno più il decimo degli stranieri soliti ad accorrervi sino a pochi anni indietro" (there no longer comes even the tenth part of the visitors who used to flock thither up to a few years ago), and the lamentations over this failure of their money-bringing presence are loud and long. But what steps are taken to attract the "straniero." Let us hope that the municipalities which are now in all the chief towns giving serious consideration to the question will combine in some well-conceived, well-supported effort to "promote" Italy's natural as well as traditional and artistic advantages, and so attract foreign sojourners to health-resorts worthy of really civilised preference.

---

[1] THE LANCET, May 29th and June 5th and 12th, 1897

WE chronicled briefly in THE LANCET of Jan. 28th the appointment of Sir WILLIAM MACGREGOR as Governor of Lagos, mentioning that he is an M.D. of Aberdeen University and that he at one time filled important medical appointments both in Scotland and in colonial dependencies. We do not know if our readers recognise that it is not a very unusual thing for medical men to attain to high position in the State and to serve their country efficaciously in diplomatic directions; we are certain that the general public is quite ignorant of the valuable political work which has been and is being done by the medical profession.

British rule in India had its origin in certain concessions and trading monopolies granted by the Emperor of DELHI to one Dr. GABRIEL BROUGHTON, a surgeon of the East India Company's ship *Hopewell*. Out of the Emperor's complaisance toward a medical man sprang the Anglo-Indian Empire by processes which many historians have traced, and no historian more skilfully than Sir JOSEPH FAYRER in an address delivered at the first dinner of the Indian Medical Staff some two years ago. How far the empire in more recent times has drawn largely upon the services of medical men we have no need in these columns to proclaim. The work of such men as Sir JOSEPH FAYRER himself, of MACNEIL, HAMILTON, and FALCONER — to mention only the first names which occur to the recollection —has been most powerful for the consolidation of our imperial interests as well as most active for the betterment of the subject people, while every member of the Indian Medical Service feels that he has a double duty to perform—that of a medical man and that of a pioneer of British rule. Similarly English medical men have played an important part in the establishment of diplomatic and commercial relations between their country and Russia. The foundation of the Russian Company and the consequent development of trade between London and Moscow were largely due to sympathetic feelings inspired in the Muscovite Court by two English body-physicians to the reigning sovereigns—MARK RIDLEY and ROBERT JACOB, as has been told at some length in our columns.[1] In more recent times Sir RUTHERFORD ALCOCK, Sir JOHN KIRK, and Dr. JAMESON have worked in an analogous manner. Sir RUTHERFORD ALCOCK, who died but recently, left the Army Medical Service for diplomatic employ about 50 years ago and became successively British Consul at Canton, Minister Plenipotentiary to the Japanese Court, and finally Superintendent of Chinese Trade. It is the result of his work under the last title which has incited other nations to their recent action in China, for they saw what good might accrue to them from well-regulated traffic with the Celestials. Sir JOHN KIRK, who has now retired, was medical officer to LIVINGSTONE'S expedition to Eastern Africa and became Political Resident at Zanzibar and finally Commissioner at the Niger Coast. Dr. JAMESON'S success as civil administrator of Rhodesia has been clouded by his military invasion of the Transvaal, but the value of his political services has been and may yet again be very real.

There recently died at Alexandria Sir JAMES MACKIE who played a very prominent part in Egyptian affairs and who in a marked manner showed that the good diplomatist is born and is not necessarily made in Downing-street. His career forms another example of the valuable political work which may be done by the medical man. Sir JAMES MACKIE went to Egypt in 1861 as a very young man and was seen by the English residents to be made of sturdy stuff. He was appointed surgeon to the British Consulate before he was 30 years of age, and 10 years later he became sole British Delegate to the Board of Health, a board regulating under a complicated system of international control all Egyptian arrangements with regard to maritime sanitation and quarantine. It need hardly be said that his political position was a delicate one when we remember that the right of England to be in Egypt at all is seriously disputed by some English statesmen (and during MACKIE'S lifetime was disputed by many more), is strenuously denied by France, and is not very vigorously supported by the Egyptians themselves or by their over-lord, the Sultan of TURKEY. MACKIE'S work, however, was good; he was so ready to incur all responsibility for his views and to expend endless time in proving their soundness that his presence on the Board soon became welcome to all parties, and his success there proved a splendid argument in favour of English interference in Egyptian affairs. Instances might be multiplied, and we are aware that many names have been omitted that might well have been included, but enough has been said to show that the medical profession has furnished to the empire many valuable political agents—to give them the baldest description to which their services entitle them.

Annotations.

"Ne quid nimis."

THE GOVERNMENT AND VACCINATION

ON Feb 10th Mr Balfour said in the House of Commons that it was not the intention of the Government to bring in any vaccination legislation in the course of the present session To our mind this comes perilously near the breaking of a pledge and we think that the action or neglect of action may cost the Government dear It was generally understood that the Government would bring in a Revaccination Bill at an early date if the Bill of last session was allowed to become law *Undoubtedly many opponents of* the present Act were persuaded to hold their hands by what they construed to be a definite promise of some measure of revaccination and we shall have no sympathy with Lord Salisbury s Administration if the just chagrin of such legislators should be visited upon it

THE PERIODICAL EXAMINATION OF SCHOOL CHILDREN FOR DIPHTHERIA AND OTHER INFECTIOUS DISEASES

A THOROUGH and interesting report has recently been issued by Mr J D Windle, the medical officer of health of the Southall Norwood Urban District on the prevalence of diphtheria in that place The several factors which may be operative in the spread of diphtheria were all carefully examined by Mr Windle and after weighing the evidence he concludes that the spread and continued prevalence of the disease were mainly due to the co mingling of infected and non infected children at the public schools His reasons in support of this conclusion are—(1) the cases were almost entirely confined to households of persons the children of whom attended the public schools, (2) in a large proportion of the invaded houses the first individual attacked was attending one of the suspected schools, (3) adults and children below school age were found to be proportionately rarely affected in the first instance and when such cases occurred it was common to get a history of previous throat illness of school attendants in the same family; (4) children *living* in better class houses and not *attending* the elementary schools showed a remarkable exemption from attack The inmates of the St Marylebone Schools with a population of about 400 susceptible children escaped entirely Acting upon this view of the outbreak the schools were closed and we are told that with their closure the notifications declined and that upon their re opening the cases again increased This sequence of events occurred on each occasion on which the schools were closed and re opened Subsequently the children in the schools were examined and some highly interesting results were obtained —results which differed very materially in the schools situated on the north side of the district from those on the south side In the infants school on the north side out of 128 scholars aged from three to seven years who were examined no less than 40 per cent were found to present enlarged tonsils and other unhealthy conditions of the throat while a large proportion had nasal discharge In the mixed school also on the north side, out of 222 children examined of from seven to 14 years of age 29 per cent had enlarged tonsils and other morbid conditions of the throat In the four schools on the south side the percentages of unhealthy throats ranged from five to 13 only This marked disproportion of unhealthy throats amongst the scholars of the schools on the north side Mr Windle attributes to antecedent throat illness from previous scarlet fever or diphtheria amongst the scholars After this the north side schools were closed, thoroughly cleansed, and disinfected and the cases of notified diphtheria dropped from 10 to zero, but increased again on re opening On closure for the Christmas holidays another fall occurred *followed by another rise on reopening Further closure* was, however, objected to by the school authorities and, as an alternative examination of the absentees was made with the view of, as far as possible, controlling the spread of the disease A conference with the school board was however, eventually arranged and it was decided that a bi weekly examination of all the scholars' throats (some 1300) should be made by Mr Windle and another medical man It was found that an examination of the throat of the hands and neck for desquamation and of the nose and ear for discharge could easily be carried out Every child with even a slight sore throat was excluded from school and swabbings of the throat were obtained in all cases in which diphtheria was suspected Mr Windle states that it is impossible to speak too highly of the benefits of this systematic examination, and he thinks that its great value lay in the discovery of unreported cases the presence of which is the chief factor in disseminating *disease through the medium of schools* Such examination however, should be continued in non epidemic times and especially on the reassembling of the scholars He regards the absence of objective signs as one of the reasons why diphtheria is perhaps more prone to spread through the agency of schools than are easily recognisable diseases such as scarlet fever, measles, and whooping cough We congratulate Mr Windle upon his report and we are pleased to see that the sanitary authority and the school board have been able to work together harmoniously

LYING-IN CHARITIES AND THE MEDICAL PROFESSION IN HULL

THE medical profession has always been friendly and considerate towards lying in charities Men like Dr Robert Barnes have given their time and influence to them both as patrons and physicians, and busy practitioners in London and the provinces have accepted office in them and been at the beck and call of the midwives whenever they had a difficult case If this amicable relation is to continue there will have to be more scruple on the part of the maternity charities than has been shown lately on the part of the Lying in Charity of Hull Up to 1895, according to the report of the East York and North Lincoln Branch of the British Medical Association the relation to the medical profession was such as we have stated above There was one midwife and, excluding honorary officers there were two practitioners to whom she referred and *who cheerfully helped her when necessary This* worked well About 165 cases were attended annually and the charity was a proper charity confined to fit cases In 1895 "in order to reduce the expenses of the charity the committee determined to dispense with the services of medical practitioners Two certificated accoucheuses were engaged and three *pupils were allowed, living in the house* of the Hull Lying in Charity And—and, here comes the climax of error—private practice was allowed to the midwives till at the present moment they are said to be attending about 1000 cases a year We cannot believe that such a system has been entered on deliberately in the *name of a charity* But the sooner it is exposed and the more completely it is left to its own merits the better The profession in Hull are unanimous in its condemnation We say unanimous We must qualify that word There is said to be one practitioner who is 'covering the midwives who when they get into trouble send for him or hand their puerperal cases over to the Hull Dispensary This is "covering of a very objectionable character and we must hope that when the practitioner in question realises what he is enabling midwives to do in the way of private practice and to the injury of his fellow practitioners he will quickly withdraw from an untenable position. We may look, too, to the subscribers of the charity to see that their charity is not abused by enabling their midwives to carry on a private practice. We would even appeal to the midwives to ask whether it is in their interest at this particular moment to give such an object-lesson to the public of the abuse to which they are ready to put their certificates by converting a charity into a private practice and expelling the profession from its proper position by which alone the safe and efficient practice of midwifery can be controlled. The protest of the profession in Hull is very strong, all the more so for its extreme moderation and friendliness towards the charity. There should not be one dissentient in this protest.

THE FOUNDER OF THE LANCET.

THE occasion of the issue of a cheaper edition of "The Life and Times of Thomas Wakley" has been used by the *British Medical Journal* to review Dr. Sprigge's book at length. The favourable estimate which the reviewer has been able to give cannot fail to be of great service to the book; while we, both as editors of the journal in the columns of which the work first appeared and as son and grandson respectively of the subject of the biography, desire to testify our very cordial appreciation of the terms in which the Founder of THE LANCET is described by the *British Medical Journal*. The review has been read by us with the greatest pleasure. The *British Medical Journal* reproduces in a clever wood engraving an unfinished and speaking portrait of the late Thomas Wakley which by a curious chance came into our hands while the biography was appearing as a serial in our columns. This sketch in oils is unsigned but it is evidently the work of a thoroughly good artist and the wood engraving in the *British Medical Journal* is a very successful reproduction of it.

THE CASE OF SURGEON-MAJOR H. G. GARDNER.

FROM a printed statement which has been circulated among the Members of the House of Commons we gather that Surgeon-Major H. G. Gardner, M.B., C.M. Edin., joined the Army Medical Service on Nov. 30th, 1874, and resigned his commission in October, 1890. Surgeon-Major Gardner states that while then serving in India he was refused 90 days' privilege leave to which he was entitled and which he urgently needed with a view to providing a home for his mother then 76 years of age, and that he consequently had no option but to resign; that his name appeared in the *London Gazette* of Dec. 23rd, 1890, as retired on gratuity, and was printed in the army list up to Oct. 1897 among those "liable to recall to service," and that this liability prevented his getting employment in the Egyptian Army, in the Chartered Companies, or at home. He alleges that in 1896 the late Director-General held out hopes of his being appointed to a recruiting district and possibly of his being reinstated in the service, which hopes were repeated in 1897 and confirmed by a letter of July 7th of that year by the present Director-General. Surgeon-Major Gardner states that no reason has been vouchsafed to him why he as an army medical officer should not have been employed in preference to a civilian at a time when the Army Medical Service was notoriously underhanded, especially as such employment would have been at £150 per annum, whereas in the case of civilians it is £270. Moreover, he points out that no other officers, naval or military, resigning on gratuity are liable to recall to service. Under Section 42 of the Army Act he submits that he is entitled to an inquiry into his case by the Secretary of State for War for submission to Her Majesty. Assuming the facts to be as stated we certainly think that some Member of the House of Commons might usefully introduce a question which would elicit further information from the War Office authorities on the subject.

MANNERS AND MEETINGS.

EVERYONE knows Colonel Newcome's favourite quotation, "Ingenuas didicisse fideliter artes Emollit mores, nec sinit esse feros." Unfortunately education does not always have this effect, as may well be seen by the reported accounts of a lamentable scene which occurred on Feb. 7th at a meeting of the Stockport centre of the St. John Ambulance Association. It is not seemly for members of one profession to make insinuations against members of another. From what we can gather from the report of the meeting in the *Stockport Advertiser* of Feb. 10th it was insinuated that the secretary was making a profit out of the Stockport branch of the Association, that the accounts were improperly kept, and that the secretary was not fit for his post. The meeting was apparently very disorderly and no definite conclusion was arrived at. It is, of course, always better to have matters of this kind threshed out, but a public meeting is not the best place for such inquiry. The proper way would have been to submit the question to the head offices of the St. John Ambulance Association in London.

THE OPERATIVE TREATMENT OF PERIGASTRITIS.

AT the meeting of the Société Médicale des Hôpitaux on Jan. 6th M. Merklen related the following case. A man, aged 40 years, who had had for three weeks crises of epigastric pain which radiated into the retro-sternal and even submaxillary regions, was on Nov. 10th, 1896, suddenly seized with acute pain in the left flank with all the signs of gastric perforation. Previous adhesion limited the peritonitis and a subphrenic gaseous abscess developed. He underwent operation on Dec. 2nd; nearly a litre of pus mixed with fœtid gas was evacuated and he seemed perfectly recovered. But in January, 1897, he commenced to suffer again. The pains were so great that he spoke of suicide if he was not relieved. They came on five minutes after taking any nourishment, even milk. They were increased by standing and walking. Their point of origin was the pit of the stomach and they radiated behind the sternum and into the arms to the little fingers, thus resembling angina pectoris. The duration of the attacks was from 30 to 45 minutes. After 14 months of suffering an operation was performed in March, 1898. The stomach was surrounded on all sides by adhesions which were divided, except the principal one which was very dense, of the size of a franc, and which fixed the lesser curvature of the stomach to the left lobe of the liver. The gastric wall was here thickened and indurated; this was the position of the ulcer. The patient appeared to be relieved, but pain gradually reappeared and the crises occurred again four weeks after the operation with the same localisation and the same radiation, but they differed from those preceding the operation in that they were not provoked by food and appeared solely when the patient was standing or walking; in short, gastric peristalsis was not painful, but the dragging on the gastro-hepatic cicatrix, inevitable in the standing posture, produced pain, especially after a meal when the weight of the stomach was increased by food. The patient knew well that to lie on his back was sufficient to bring the crises to an end. The causal lesion was otherwise easily ascertained, for there was a hard and painful epigastric induration of the size of a pigeon's egg. If it were not for the history cancer might have been thought of. Another operation was performed in June. The part of the liver adherent to the stomach (which was transformed into fibrous tissue) was removed with the thermo-cautery and the wound was closed with catgut sutures. The gastric ulcer was resected in the same way. Relief ensued. As to the diagnosis of perigastritis M. Merklen stated that persistence of pains in spite of treatment was an indication and induration in the gastric region a proof. The pains seemed to be of two kinds—those produced by food and those produced by standing. The latter were explained by the site of adhesion which usually was gastro-hepatic. M. Merklen thought that perhaps on the radiation of the pain—retro-sternal, cervical, and brachial—might be based the conclusion that an ulcer at the cardiac extremity existed with perigastritis involving the solar plexus. The treatment consisted in detaching or dividing the adhesions—a simple operation, or in resecting the ulcer and inflammatory new growths—a serious and difficult operation

INFLUENZA.

THERE is no longer any doubt that we are face to face with an outbreak of typical influenza. Medical men are beginning to feel that strain on their time which they have experienced five or six times in the last eight years. So far the cases are not of that grave kind with which we have been too familiar in several years, but they are unmistakeable. The symptoms including the sharp pyrexia often setting in very abruptly with characteristic pains, and followed by disproportionate prostration, are unmistakeable whether with or without catarrh and whether this be tonsillar, bronchial, or intestinal. We can only hope that the epidemic will keep within moderation and that the cases will not assume a more serious form. One great point in the treatment is the thorough ventilation of the sick-room and of houses in which cases occur. Where this is neglected the cases multiply and the severity of them seems to be increased.

CRIMINAL STATISTICS FOR 1897.

THIS important blue-book has recently been issued and, to quote the opening words of Mr. H. B. Simpson's introduction to it, "the criminal statistics for 1897 present similar features to those noticed in the reports on the statistics for recent years." That is to say, the decrease in serious crime in England and Wales continues and in no particular class of indictable offence is there any increase which has not been already noted in previous years. It must be remembered that the decrease in crime is an actual diminution in the number of cases for the year, not merely a diminution when the figures are viewed with reference to an increasing population. As an instance we find the number of persons sent to trial for indictable offences in 1897 to have been 11,215, a number less than in any year since 1857, except 1896, when it was slightly lower, while the average number in the five years preceding 1897 was 11,816. Again, if indictable offences dealt with summarily are added the general diminution is still observable, although it is less marked than in the case of those more serious charges dealt with at assizes and quarter sessions. At the same time there is an increase, although not a large one, in the tale of what are known as "minor offences." An example of an indictable offence which increases instead of diminishing in frequency is that of attempted suicide. For this 190 persons were sent for trial in 1897, which is less, indeed, than in 1896 when the figures were 208, but is higher by two than the average of the five years 1893-97, while the number of suicides actually carried out in 1897 was 2785 as against 2639 in 1896. Apparently a very large number of cases of attempted suicide are reported to the police but not considered of serious import or are for other reasons not brought to trial, for in an interesting table which shows the incidence of indictable offences with regard to particular months of the year we observe that in July, 1897, the police return 245 cases, as against 235 for June, 1896, the worst month of that year in this respect. It will be worthy of note in the corresponding table in the next volume of these statistics what effect, if any, may appear to have been exercised by the great autumnal heat of the past year. Commenting generally on the introduction to the statistics we may say that it contains much excellent and valuable matter, but we regret for our own purposes of reference that the table formerly given in it of cases of murder in which capital punishment was inflicted has now for some time been omitted. The table to which we refer indicated briefly the nature of the crime and the manner in which it was committed. To it was appended a list of the names of those who had been sentenced to death for murder but who had been subsequently respited, while before 1883 in the case of these a note as to the nature of the crime was also added. Had these lists been continued they would have been of use to others as well as to ourselves who have had to deal recently with the questions of punishment in cases of death brought about by illegal operations or in the execution of felonious acts without the intention to kill. Presumably statistics of these crimes will be called for by Parliament shortly, but had they been consistently given in the blue-book on crime they would have been accessible already. Apart from this, consistency of form in an annual publication is always convenient, although we admit the value of any improvements which may suggest themselves or which may be suggested from time to time. We ourselves suggest for the benefit of the compiler of next year's introduction that the addition of page references where tables are quoted would facilitate the consideration of his work.

ON THE FORMATION OF SUGAR FROM EGG ALBUMEN.

A POINT of considerable importance both in chemistry and physiology, and undoubtedly also in medicine, is to determine whether sugar is contained in a molecule of albumin, since in a severe attack of diabetes man forms sugar in his tissues probably through the intermediation of this substance. This question has been attacked by M. Ferdinand Blumenthal who has communicated the results of his researches to the Académie des Sciences in a paper read before that body on Jan 9th of the present year. Passing over negative statements M. Blumenthal refers to the work of Dr. Pavy on the Carbohydrates, who believes he has obtained sugar at the expense of albumin. But inasmuch as he precipitated albumin by alcohol it follows that the sugar contained in eggs remained adherent to the albumin and as he has not made any attempt to separate the two his experiments do not solve the difficulty. More recently Dr. Krawkow, in operating on albumin free from sugar, found that after heating it with hydrochloric acid he obtained carbohydrates which gave with phenylhydrazine an osazone which melted at from 182° C. to 185° C. But as no carbohydrate is known to produce an osazone having this melting point these experiments cannot be regarded as settling the question. Hofmeister also obtained in 1897 0·1 gramme of osazone from one gramme of albumin, but has not given its characters in detail. Last year (1898) M. Blumenthal submitted white of egg to the decomposing action of a solution of baryta hydrate in the first instance and then of hydrochloric acid, and by this means obtained a liquid which reduced Fehling's solution, and gave with acetic phenylhydrazine an osazone the melting point of which was between 194° C. and 204° C. As this osazone was only slightly soluble in hot water, pure cold alcohol and ether, and being opposed to the diagnosis of croupous pneumonia, though their diminution, or even their absence, does not necessarily imply that the case is an example of the disease. As croupous pneumonia is the only pulmonary disease in which diminution of chlorides occurs to any appreciable extent an examination of the urine may prove of great value in the diagnosis of pneumonia from other causes of consolidation of the lung, and from empyema, pleurisy with effusion, &c. It must, however, be remembered that the chlorides may be strikingly diminished in some cases of disease of the stomach—notably in dilatation.

MUNICIPAL BACTERIOLOGY.

IN the annotation on the above subject in our issue of Feb. 11th we remarked that Camberwell had provided for bacteriological examinations in certain infectious diseases and we did not see why other parishes should not do likewise. Mr. S. R. Lovett, the medical officer of health for the St. Giles's District, informs us that his vestry have recently undertaken to provide for the bacteriological examination in suspected cases of diphtheria or enteric fever. Tubes and swabs are provided and the examination is undertaken in the conjoint laboratories. Fees are paid by the board of works for the district. Mr. Lovett informs us that he believes that similar arrangements have been made in the adjoining districts of the Strand, Holborn, and Clerkenwell. We are very glad to hear this and we hope that it will not be long before similar arrangements are in existence throughout the metropolis. The vestry of St. George-the-Martyr will perhaps now reconsider its decision.

ANOTHER ABORTIONIST.

AGAIN the solemn farce has been played through to the last scene with the usual correctness of scenic accessory and costume, including the black cap. This time the person who was condemned to death without the least likelihood of the sentence being carried out (she has since been reprieved) was an elderly woman named White who apparently for many years had practised as a midwife and had been ready to procure or to attempt to procure abortion when solicited to do so. Her patients came from the ranks of the poor and ignorant and her stock-in-trade consisted of two or three catheters, usually kept in the coal-cellar lest the police might with sudden inquisitiveness pay a domiciliary visit. No attempt seems to have been made to cleanse these instruments between one occasion for their use and the next one, and the medical evidence at the trial was to the effect that had not the septic condition of one of these filthy catheters set up inflammation in an accidental wound no abortion would have resulted from the operation performed. The death of Alice Birmingham is an example of the temptations and dangers to which women of the lower classes are exposed. The fate of Jane White may be an equally instructive object-lesson. Unfettered by any law to prevent her she practised midwifery upon such women of her class as might choose to employ her. Even the proposed legislation with regard to midwives hardly touches her. Her *clientèle* if satisfied of her skill would not have cared if a Midwives Board did not agree with them. She would have been unable to use the convenient title of her class, but beyond that the absence of her name from the roll might have served to advertise her want of scruple. Apart from this, freedom to do as she chose and a certain acquired familiarity with her subject matter—the kind of familiarity which, coupled with absolute ignorance, breeds contempt for danger—made her an abortionist when her services as such were required; and but for a rash conversation of four years before, recalled by a friend of the deceased, Jane White's victim would have remained in her grave and Jane White herself would still be plying her trade. The position is consistent enough. In a country in which every quack may practise general medicine or surgery until he kills someone there is no logical reason why a woman who cares to run a small risk should not do the same in a special department without her qualifications or her methods being subjected to the smallest inquiry. The Home Secretary stated in reply to a question in the House of Commons on Feb. 14th that the subject was engaging his anxious attention. We welcome the information.

ACCOMMODATION IN THE RABBIT.

IN a recent number of the *Ophthalmic Review* (No. 204, 1898) Mr. Priestley Smith gives some interesting experiments which he has made on the capability of the rabbit to effect accommodation in the eyes. *Primâ facie* we should have thought no doubt could exist. Rabbits are as quick as most animals in perceiving the sportsman and they must surely be capable of distinguishing near objects, such as the herbage and their own young. Nevertheless, it appears that Beer and others have been unable to satisfy themselves that these animals possessed any form of accommodation, though they had no difficulty in observing it in others. Mr. Priestley Smith by examining the eyes in rabbits which had been dosed with chloroform and chloral hydrate and in animals which had been decapitated has been able to demonstrate that these animals possess a range of accommodation of about 4 D. which though less than Hess and Heine showed to be present in apes, in which it amounted to 12 D., is yet considerable.

THE HAMPSTEAD HOSPITAL.

ON the afternoon of Feb. 5th a large meeting was held in FitzJohn's-avenue for the support of a scheme of starting a general hospital in Hampstead. The chair was taken by Sir Richard Temple who said that in the unavoidable absence of Sir Henry Burdett the committee had asked one of the consulting surgeons of the existing hospital, Mr. Edmund Owen, to lay the question fully before the meeting. Mr. Owen said that the fact of Sir Henry Burdett being, as showed by the letter just read from him, in favour of the proposed building would be a certificate to the public that it was actually required. He (Mr. Owen) was of opinion that a municipality with 70,000 inhabitants certainly deserved a hospital, especially when, as was the case with Hampstead, its geographical situation rendered the conveyance of sick and injured patients to one of the nearest of the general hospitals a matter of great inconvenience. From a long association, as consultant, with their present and inadequate building he could assure the meeting that a larger one was absolutely necessary—one containing, he would suggest, 50 beds. Though it need not be an expensive building it should be artistic and decorative, otherwise it would not be worthy of the picturesque and important district which it was to serve. He spoke very strongly against the establishment of an out-patient department in the new hospital, affirming that the outdoor charities, clubs, and dispensaries in the district were fully sufficient for all purposes, and that the creation of an out-patient department would lead to endless expense and inconvenience to the hospital and would encourage throughout all parts of the parish the habits of thriftlessness and pauperisation. Sir Samuel Wilks, consulting physician to the present hospital, also expressed the opinion that the existing institution on Parliament Hill was not worthy of so important a district as Hampstead. He spoke of the advantages of decentralisation, and remarked that as he drove through the various suburbs he found each district properly equipped with its own public institutions, its theatre, and its hospital. He thought that the time had fully come for Hampstead to acquire a site and erect upon it a hospital of moderate size. Mr. E. Bond, M.P., Mr. J. S. Fletcher, Mr. Wightman, Mr. S. Figgis, and Mr. Malcolm, the honorary treasurer, also spoke, and Mr. Outhwaite, the honorary secretary, announced at the end of the meeting that upwards of £2000 had been promised for the scheme.

"CAVENDISH."

THE death is announced of a member of the medical profession who was very widely known in other fields. We refer to Mr. Henry Jones, M R C S., of world-wide renown as "Cavendish," the authority on Whist. Mr. Jones studied at St. Bartholomew's Hospital and was in general practice from 1852 to 1869. He was a member of the Court of the Apothecaries' Company but for the last 30 years he made the exposition of indoor games the pursuit of his life.

THE PLAGUE SHIP "BHUNDARA."

WE commented some weeks ago on the unfortunate attitude of the Government of Zanzibar and of our East African Protectorate in dealing with the s s. *Bhundara* which was carrying coolies and a cargo of rice from Karachi to Mombasa and on board of which there had been several cases of plague. First they wanted to repel the ship altogether, not caring, apparently, what became of her or of the 1000 people on board, then they wanted to impose restrictions upon the ship and upon those she carried which savoured of the useless quarantine observances of a past generation; and, lastly, they wanted to disinfect her cargo, which process, as is well known, has no medical or scientific significance. But, owing to appeals from India and to the decided action of the Foreign Office, these intentions were frustrated, and we are glad to find from a public announcement by Sir James L Mackay that although there was a regrettable delay yet in the end the rules of the Venice Convention were observed and the general policy of Her Majesty's Government was maintained. Thus this incident terminates satisfactorily. But it should be a lesson to the Governments of those portions of our Empire who want to retain reasonable freedom for their own commerce that they should also act reasonably when arrivals in their own ports are concerned Perhaps there are few parts of our Empire where this rule needs more observance than in India whence complaint came as to the treatment of the *Bhundara*. If ships leaving ports of India are to receive treatment on the lines of the Venice Convention all the various Governments of India should take care to act on the same lines as regards both departures from, and arrivals at, their own ports.

QUARANTINE IN THE COLONY OF VICTORIA.

WE have received the report of the Board of Health of the colony of Victoria for the years 1896–97. This report which has been presented to both Houses of the colonial Parliament and is published by the Government printer in Melbourne is not based on a compilation of vital statistics, but is a review of the work done by the Board with the object of protecting the public health and of promoting hygiene in the colony. The board consists of two nominated and seven representative members, Dr. D. Astley Gresswell, one of the nominated members, being the chairman. Perhaps the most interesting of the various sections of the report is the one on the subject of quarantine After having considered the regulations of the English Local Government Board for dealing with cholera, yellow fever, and plague, the Victoria Board of Health submitted to the colonial Minister of Health a resolution to the effect:

> "That it would not be desirable to modify the procedure at present followed in regard to quarantining for cholera, yellow fever, and plague in order to bring it into accord with the regulations now in force in the United Kingdom, and that in this connexion attention be invited to the following matters: 1. The procedure in Victoria differs from that under the regulations referred to by reason of the fact that whereas all persons on an infected ship are placed in quarantine in Victoria only those who are found to be or suspected to be infected are so dealt with in the United Kingdom, the rest being liberated after giving their names and addresses. 2. A system of medical supervision as efficient as that required under the regulations in the cases of persons liberated from an infected ship is scarcely practicable as yet in this colony. 3 . 4 The system followed in this colony does, in the opinion of the Board, materially reduce those risks without seriously deranging commerce, whereas for the United Kingdom the same system would be wholly impracticable."

During the period under review three steamers were quarantined for small-pox and one for Java fever.

PURE BEER.

THE report of the Beer Materials Committee is not calculated to lead to a new legal definition of beer such as must have been confidently hoped for by Mr. (now Sir) Cuthbert Quilter when he introduced his Pure Beer Bill in 1896. To demand that beer should be a fermented infusion of malt and hops only would involve "interference with business" while "it is not possible to determine by chemical analysis with sufficient certainty . .... whether malt adjuncts have or have not been used except in cases where excessive proportions of such adjuncts have been employed." The evidence of analysis, in other words, cannot be relied upon for obtaining a conviction. The committee are convinced also that "no deleterious materials are introduced into beer by way of substitutes for hops." The strong tendency of the report is, in fact, to negative all those proposals in favour of restricting the materials used in the elaboration of beer to malt and hops only in accordance with the honest formula used long before this age of substitution. Thus as long as substitutes are wholesome their employment is to be regarded as legal. We have before urged that it should be possible to direct legislation on lines which would ensure to the purchaser his right when he asks for beer to obtain beer and nothing but beer—i e., a liquor brewed exclusively from malt and hops Anything else should be called by another name, just as it is insisted on that butter substitutes shall be called margarine and not butter. We quite believe that the "adjuncts" and "substitutes" used in beer are not generally deleterious, but that is not the point at all, although it is an important one. Adjuncts and substitutes are not the materials in which beer had its origin and therefore to supply the purchaser with a fermented liquor made with these or in part with these is to supply him with an article not of "the nature, substance, and quality demanded" The only step which the committee suggest towards reform is that the brewing industry should be brought under stricter control "than is exercised in the case of most other industries."

THE PROFESSOR OF PATHOLOGY IN CAMBRIDGE UNIVERSITY.

DR. GERMAN SIMS WOODHEAD, *M.D*, *F.R.S. Edin.*, has been elected professor of pathology in Cambridge University in the room of the late Professor Kanthack. We congratulate Dr. Sims Woodhead upon his selection for the post and the University upon having secured so admirable a man to do their work, one of the few pathologists in the kingdom to whom the post, honourable and desirable as it is, is hardly promotion. It is unnecessary to do more than allude to Dr Sims Woodhead's qualifications for any appointment in pathology which he might seek. His literary work and his practical work as Director of the Laboratories of the Conjoint Board of the Royal College of

Physicians of London and the Royal College of Surgeons of England, have alike shown him to be an original and resourceful master of research. He takes with him to Cambridge the good wishes of all the great number of medical men to whom his position at the Conjoint Board made him known, while we may be certain that he leaves that Board sincerely regretting his departure.

THE MIDWIVES BILL.

As will be seen from our Parliamentary Intelligence a "Bill to Promote the Better Training of Women as Midwives and to Regulate their Practice" has been introduced (by Mr. J. B. Balfour) and read a first time in the House of Commons. The second reading has been put down for Wednesday, April 12th, but on that day two other measures have precedence and it is not unlikely that their discussion may occupy the entire sitting to the exclusion of the Midwives Bill. At any rate it will be well for those who are interested in the subject—and what member of the profession is not?—to make careful note of the date.

DR. P. W. LATHAM who has so long held office as physician to Addenbrooke's Hospital, Cambridge, has signified his intention of retiring from office at Lady Day. In a graceful circular letter he says that while making the announcement with the greatest possible reluctance he has arrived at the decision in accordance with the rule prevailing at all London hospitals that at the age of 65 years a hospital physician or surgeon should vacate his post. Dr. Latham will continue his private practice amid the good wishes of many generations of Cambridge medical men.

A PLEASANT conversazione was given by Sir William and Lady Mac Cormac at the Royal College of Surgeons of England on Monday, Feb. 13th. The company included a large number of ladies. On the following day H.R.H. the Prince of Wales and a distinguished company were present at the College to hear the Hunterian Oration, which was delivered by the President of the College, Sir William Mac Cormac, and which is published in full in our present issue. Subsequently His Royal Highness dined privately with the President and Council.

THE *Times* states that "the army medical authorities have a grievance against the War Office in connexion with the recent operations in the Soudan. It is alleged that no notice was taken of an application for a hospital ship to proceed to Alexandria in time to receive the soldiers invalided from the front, and that when a second application was made—the provision for treating the sick being altogether inadequate—the reply was that it was too late for anything to be done in the matter."

MR. T. GARRETT HORDER has given notice to ask the Council of the Medical Defence Union to recommend the members to pass a resolution at the next annual meeting to the effect that in future no one shall be eligible for membership who holds office in any medical aid association. We think that the Council of the Medical Defence Union will be doing good service by such a departure.

THE first Hunterian Society Lecture will be delivered by Mr. Charters J. Symonds, F.R.C.S. Eng., in the London Institution, on Feb. 23rd, at 8.30 P.M. The subject of the lecture will be the Value of Individual Symptoms in Perforative Peritonitis, more especially in regard to Operation. Members of the profession are invited to attend.

MR. W. J. COLLINS, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng., ex-Chairman of the London County Council, has been appointed by the President of the Board of Agriculture to represent the Council on a Departmental Committee to inquire into the Diseases of Animals Act.

A PLAGUE scare appears to prevail in Pretoria as a result of the recent case of plague discovered in a coolie to which we referred last week. The scare is probably quite irrational but we hope all possible means of precaution against infection will be quickly taken.

H. R. H. THE PRINCE OF WALES has consented to become President of the National Association for the Prevention of Consumption and other forms of Tuberculosis.

THE first international congress of medical officers to life assurance companies or institutions will take place in Brussels in September.

THE death, in his seventy-second year, is announced of Mr. Charles Bader, M.R.C.S. Eng., consulting ophthalmic surgeon to Guy's Hospital.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE fiftieth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Feb. 7th. The commissioners present were the Chairman (Lord Llandaff), the Right Hon. John W. Mellor, Sir John Dorington, Sir George Barclay Bruce, Mr. de Bock Porter, Mr. Robert Lewis, and Major-General Scott. The whole of the sitting was occupied by the examination of Sir Henry Knight who put in tables relating to the financial state of the Southwark and Vauxhall Company, of which he is chairman.

At the commencement of the proceedings Mr. PEMBER, Q.C., on behalf of the East London Waterworks Company, said that Mr. Crookenden, the secretary of the company, who had given evidence at the last sitting had made some mistakes in the figures which he gave. The profits of the East London Company for the half year ending Midsummer, 1898, should have been given as £90,182 10*s.* 5*d.* and the nett profits £67,609 19*s.* 3*d.*

Mr. CLAUDE BAGGALLAY, Q.C., on behalf of the Southwark and Vauxhall Company said that Sir Henry Knight did not assent to the evidence given by the witnesses of the London County Council with regard to capital expenditure, obsolete capital, and matters of that sort, but he did not wish to go into those matters unless it was the wish of the Commissioners that he should do so. He was, however, prepared to deal with the question of the revision of capital on which Mr. Gomme had given evidence at one of the earlier sittings of the Commissioners.

Sir HENRY KNIGHT, in answer to the CHAIRMAN, said that the debentures of the Southwark and Vauxhall Company were trustee stocks and in answer to Mr. MELLOR he said that trustees largely invested in them.

Mr. BALFOUR BROWNE pointed out that under the Trustee Act of 1893 the stocks of a water company which had paid 5 per cent. for 10 years became a trustee stock.

In answer to the CHAIRMAN the witness said that he thought it would not do in the case of purchase for the shareholders of the company to obtain redeemable debentures. There was always a considerable difference in the market price of redeemable and irredeemable stocks to the disadvantage of the former. The witness said that in his opinion if the water companies' undertakings were managed by the London County Council an economy of £50,000 a year would not be effected in the cost of management. On the contrary, he thought that an increase of the expenditure would take place. With regard to the interview which the witness had had with Sir Arthur Arnold on which evidence was given by the latter at one of the earlier sittings the witness said that he had expressed an unwillingness to sell and that no terms of purchase were mentioned If the undertakings were bought he thought it should be under the Lands Clauses Acts and the precedents established under those Acts The witness said that the companies had no "depreciation account The water mains lasted a very long time No depreciation was admitted to exist with regard to the value of the buildings, the witness said that these were kept constantly repaired and were always considered as good as new With regard to the cost of new mains a considerable amount of time was spent in exactly determining what the witness meant If a main of a certain size is taken up and a larger one put in its place some of the money which the new main costs is paid from the current profits of the company and some is charged to capital account If an old main is replaced by a new one of the same size the whole amount is paid for out of the profits no sum is added to the capital account If for example an old pipe which had cost £500 were replaced by one which cost £2000 of this sum of £2000 thus spent £1500 would be added to the capital account and the other £500 would be paid out of the revenue The value of land as it appears in the capital account is the same as the price which was originally given for it With regard to the scheme of purchase suggested by Mr Banbury the witness thought it was a rough and ready scheme and that it would have to be altered in order to make it just and workable

In answer to Sir JOHN DORINGTON the witness said that purchase should take place by arbitration

In answer to the CHAIRMAN the witness said that the present storage capacity of the company amounted to 456 000 000 gallons Since the statement of the company putting it at 136 000 000 gallons reservoirs having a capacity of 320 000 000 gallons had been added

In answer to the CHAIRMAN the witness said that he thought that some economies might be effected if the companies became federated, at about which period of the sitting the Chairman had considerable trouble in obtaining answers from the witness and he complained of the time wasted in beating about the bush

In answer to Sir JOHN DORINGTON the witness said that he did not propose that representatives of public bodies should be on such a confederation In his opinion an area over which the confederation should have power should be settled by experts but he thought that it should be a very extensive tract extending beyond the Chiltern Hills on the north to Reigate hills on the south to the Medway on the east, and as far as Reading on the west The private companies which now existed in Hertfordshire should be taken into this confederation

With regard to the question of control the witness said in answer to the CHAIRMAN, that he could not suggest any additional measure which would be useful to water consumers He was afraid that control might be extended to such an extent that the whole of the responsibilities would be taken from the companies hands and put on to somebody else

On the question of the advisability of taking flood water the witness said that he had lived on the banks of the Thames for 40 years had watched the floods closely, and concluded that it was safe to take the water from four to six days after flood He did not think that there was anything injurious in flood water but as business men they would not take thick flood water because it would only mean putting so much deposit into their storage reservoirs and so much on to their filter beds

In answer to the CHAIRMAN the witness said that the company did not always charge the full statutory price for water and gave as an example the case of a wharf of which the rateable value was £11 317 and the amount on which the water rent was levied was £1886

In answer to Mr DE BOCK PORTER the witness said that water was only used in a very small part of these premises that is, just the counting house part He did not know whether there was a well on the premises

In answer to Major General SCOTT the witness said that they proposed to construct reservoirs at Molesey to give a storage capacity of 1 176 000 000 gallons There were to be two reservoirs one containing about 580 000 000 gallons and the other the remainder

Major General SCOTT pointed out that a single reservoir at Staines would occupy a much larger space than the whole area which the Southwark and Vauxhall Company proposed to use for two storage reservoirs and suggested that there was economy in a large reservoir, The witness said that the advantage of a reservoir of moderate capacity was that in case of cleaning a smaller area was thrown out of use

In answer to Mr DE BOCK PORTER the witness said that he was interested in the adventure of bringing sea water to London for watering roads, cleansing sewers, and baths; It would also be useful for putting out fires In answer to the CHAIRMAN the witness said that he could not "tax his memory as to whether the experiment of throwing salt water on fires had been made

With regard to the flow of water which had to be maintained in the Thames the witness said he wished to satisfy the Commissioners that 100 000 000 gallons a day was a sufficient flow and the CHAIRMAN asked what proof he had in favour of the truth of that theory The witness replied that during part of last year the flow was diminished to an amount less than 100 000 000 gallons a day and that there was no material complaint

The CHAIRMAN pointed out that Mr Moore of the Thames Conservancy Board had shown that people were sick of complaining because it was of no use

In answer to Mr BALFOUR BROWNE who examined on behalf of the London County Council the witness said that he did not object to control on the ground that the company which he represented would have to spend money which would not be remunerative he thought that should a competent authority after inquiry prove that their works were deficient they would willingly submit to any requirements which would tend to make all the works efficient It would be unreasonable and impossible for the Local Government Board to compel the West Middlesex Company to supply Wandsworth, Putney and Battersea places which are within the statutory limit of supply of that company There was no reasonable control that could be imagined which he feared on behalf of his company

Mr BALFOUR BROWNE suggested that the Local Government Board might have power to compel the company to have new sources of supply or to make reservoirs

Major General SCOTT pointed out that in the year 1852 such a course was taken inasmuch as a transfer of the intakes of the companies was insisted upon under the Act of that year

With regard to the question of obsolete capital Mr BALFOUR BROWNE pointed out that the auditor appointed under the Act of 1871 had stated in his first report that as regards the Southwark and Vauxhall Company he had come to the conclusion that capital should be relieved, to the extent of £33 082 8s 8d and that the accruing revenue should be charged therewith in addition to an outstanding claim of £10 722 It was therefore evident that the company had wrongly charged capital with a sum of over £33 000 The witness said that the award of the auditor had been carried out by the company and the money had been paid by annual instalments

Mr BALFOUR BROWNE called attention to the fact that recently a difference of opinion had existed between the auditor of the Local Government Board and the company with regard to the way in which the cost of relaying a main should be paid The witness spoke of a slight 'weeping at some of the joints as being the cause of the difference of opinion and said that the matter had been settled to the satisfaction of the Government auditor

Mr BALFOUR BROWNE pointed out another case in which there was a difference of opinion between the company and the auditor with regard to a sum of £1700, and the witness suggested that this fact showed the excellent supervision which already existed which made it impossible for them or any other company to carry to capital a sum which they ought not to put there

Mr BALFOUR BROWNE asked the witness at what depth the mains were laid and whether it was not a fact that they had suffered very much from the frost of 1894 The witness replied that they were gradually lowering the mains and that some of them were originally laid too near the surface Should purchase be decided on the witness thought that it should be done by arbitration He did not agree with one of the witnesses of the London County Council who suggested that there would be a large saving in the matter of directors' fees if the managed by that body The important decision in Grand Junction Waterworks the profits of the company. In 1883 they amounted to over £80,000 a year and after that decision they went down to £55,000 and to £54,000 in the year 1886.

Lord ROBERT CECIL, on behalf of Hertfordshire, said that he had a profound distrust of Sir Henry Knight's scheme of confederation. He wished to guard the interests of Hertfordshire by saying this, but he had no wish to elaborate the matter.

In answer to Mr. DE BOCK PORTER, the witness said that in relaying the mains a part of the cost was charged to revenue and part to capital. A small proportion was charged to capital because they "had value for it" in the protection which was thereby afforded in case of frost.

With regard to the amount in the capital account for land the witness said that the amount paid originally for land at Battersea which was about £250 an acre still stood in their accounts at that price, although that sum was insignificant as compared with the present value of the property.

THE fifty-first sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Feb. 13th. The Commissioners present were the chairman (Lord Llandaff), Sir John Dorington, Sir George Barclay Bruce, Mr. de Bock Porter, Mr. Cripps, Q.C., Mr. Robert Lewis, and Major-General Scott. The witnesses examined were Mr. J. W. Restler, engineer to the Southwark and Vauxhall Water Company, and Mr. Edmund Boulnois, M.P., Chairman of the West Middlesex Waterworks Company and of the Staines Reservoir Committee. Statistics were put before the Commissioners with regard to the increase of population in the Southwark and Vauxhall Company's district and with regard to the complaints received by that company from their customers from the year 1880 to the present year. In addition to these tables a statement as to the present condition of the Southwark and Vauxhall Water Company was put in. This statement gave an account of the sources of supply, of the area of supply, and a brief description of the various stations of the company, of which a full account has already appeared in THE LANCET.[1] Mr. Restler said that the area supplied by the Southwark and Vauxhall Company was 50½ square miles in extent and that the population amounted to 819,901. The West Middlesex, the Lambeth, and the Kent Companies had power to supply within parts of their statutory area, and the Lambeth Company were authorised to supply no less than four-fifths of their entire area. Since the year 1852 no pipes had been laid by these two companies in the same streets and there was no competition between the Southwark and Vauxhall and the other companies. The Lambeth Company did not charge their maximum rate in the area which was partly supplied by the Southwark and Vauxhall Company.

In answer to Sir JOHN DORINGTON the witness said that in speaking of the area thus jointly supplied he referred to streets in which pipes of the two companies were actually laid and in use at the present time.

In answer to the CHAIRMAN the witness said that under the Act of 1884 the Southwark Company were allowed to make agreements with other companies to abolish competition. The company had very few complaints with regard to the quantity and quality of the water which they supplied to their customers. During the year 1898 there was one complaint as to the quality and the amount of complaints received as to the quantity supplied were one per day per half million of persons supplied. During the drought of last summer there was no lack of water. Most of the cases in which complaints were made were due to defective fittings in the houses of the customers, and very frequently to the fact that the ball-cocks were out of order. During the months of September and October, 1898, the Southwark Company was able to supply about 5,000,000 gallons per day for the use of the customers of the East London Company.

The CHAIRMAN made an inquiry with regard to the supply of water containing 16,000 bacteria per cubic centimetre and the witness replied that an investigation was made into the matter and the sand of the filter was examined but nothing was found to account for the presence of the large number of bacteria. The filter had since been worked satisfactorily.

With regard to division of the area supplied by the Southwark Company between the counties of Surrey and Middlesex the witness said that such an arrangement would not tend to economy. With regard to the question of whether the water companies ought to be made liable for the consequences of frost, drought, and accident the witness gave it as his opinion that water companies should not be liable for mishaps so caused. He was of opinion that whether the undertakings were in the hands of municipalities or of private companies the effects of frost and drought would manifest themselves equally.

The CHAIRMAN remarked that the fact that the companies were able to make charges when they did not supply water seemed to require justification. The witness contended that it was not correct to say that the companies had supplied no water and that sometimes in periods of frost as a matter of fact the quantity of water actually exceeded that supplied during a period of drought. The companies gained nothing by the frost; on the contrary, the results of it were disastrous to them.

The CHAIRMAN said that it did not seem right that high supply should be charged for when it was not given.

Mr. PEMBER, Q.C., on behalf of some of the water companies, contended that that condition was attached to the statutory regulations with regard to payment.

The CHAIRMAN remarked that he received every day letters from customers of the East London Waterworks Company who complained that although high supplies were not given no exemption had been made with regard to payment.

With regard to the future demands on the Southwark Company the witness said that it was estimated that in the year 1941 they would have to give a supply of 50,000,000 gallons a day. The cost of erecting the necessary plant and of the pumping apparatus to afford this increased supply if the water were taken from the Thames and from wells would amount to something like £2,000,000.

In answer to Mr. BALFOUR BROWNE the witness said that samples of water were taken for bacteriological examination daily.

Mr. EDMUND BOULNOIS in reply to the CHAIRMAN said
that the West Middlesex Company had always been able to
furnish their customers with a full supply of water. As the
result of Lord Balfour's Commission which reported in
favour of a continuance of supplies from the Thames and
from the Lee the company had obtained from Parliamen
authorisation to construct large subsidence reservoir
which were capable of holding a fifteen days' suppl
and they had made new filter beds. More recently the We
Middlesex Company had joined with the New River and Gra
Junction Companies in the Staines Reservoirs Scheme
means of which they would be able to supply from 12,000,0
to 15,000,000 gallons of water daily in addition to th
present supply. During the present session of Parliam
the company were promoting a Bill authorising them to
a 42-inch main from Hampton to their new reservoir
Barnes. (A full account of these stations has alr
appeared in THE LANCET.[2]) When these works were ca
out the company would be able to provide for the incre
demands of their district for many years. The witness the
that the New River, the Grand Junction, and the
Middlesex Companies had adopted the most econ
method possible in uniting to carry out the Staines Res
Scheme.

With regard to the management of the London water
the witness thought that it was no disadvantage that i
[illegible] in the hands of eight different companies. The direc
water company had a great advantage over a shifting
body which was incapable of ensuring any degree
tinuity with regard to policy. If the work carried
the companies were managed by a shifting elect
it [illegible] probably lead to an increase of hig
offic[illegible] we.

The CHAIRMAN suggested that good services we
[illegible] performed by people who were not paid. "Th
County Council," he suggested, "would scorn paym
witness said that he did not think there would be
effected by an amalgamation of the companies, bu
conceive a possibility of an amalgamation for the
obtaining water from a distance. The customers
Middlesex Company were in the fortunate positi
supplied with water at a low rental. If the wa
the other parts of London were brought down to
would be necessary in order to make good the de
a "rate in aid" should be levied on the whole are

Company would necessarily suffer, for they would have to pay a rate in aid in order to lower the price of water given to the water consumers in other parts of the metropolis.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Feb 9th, the President, Sir WILLIAM MACCORMAC, Bart., K.C.V.O., being in the chair.

The Council, having been advised by counsel that the clauses proposed by the General Medical Council for the amendment of the disciplinary clauses of the Medical Acts would seriously affect the independent action of the Council of the College, resolved unanimously that the President of the General Medical Council be informed that the Council do not approve the clauses in their present form.

A letter was read from Mrs Henry Lee, offering to the College a portrait by Mr James Sant, R A., of her husband, the late Mr. Henry Lee, F R C.S. Eng , past member of the Council of the College The gift was accepted with the sincere thanks of the Council.

A letter was read from the Chairman of the Education Committee of the General Medical Council, asking for information as to the desirability or otherwise of raising the standard of preliminary education for medical students, after due notice, to that of the "Senior Local" and "Higher Grade" examinations. The subject was referred to the Committee of Management.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6730 births and 4797 deaths were registered during the week ending Feb. 11th. The annual rate of mortality in these towns, which had been 15 8 and 19 4 per 1000 in the two preceding weeks, further rose last week to 21 9. In London the rate was 22 8 per 1000, while it averaged 21·3 in the 32 provincial towns. The lowest death-rates in these towns were 11 1 in Burnley, 14 0 in Brighton, 15·1 in Croydon, and 15 7 in Norwich; the highest rates were 25 0 in Manchester, 25 2 in Oldham, 30 5 in Liverpool, and 32 4 in Preston. The 4797 deaths in these towns included 403 which were referred to the principal zymotic diseases, against 329 and 340 in the two preceding weeks; of these, 114 resulted from whooping-cough, 111 from diphtheria, 68 from measles, 49 from "fever" (principally enteric), 33 from diarrhœa, and 28 from scarlet fever. No fatal case of any of these diseases was recorded last week in Norwich; in the other towns they caused the lowest death-rates in Plymouth, Wolverhampton, Bradford, and Gateshead, and the highest rates in West Ham, Cardiff, Preston, and Sunderland. The greatest mortality from measles occurred in West Ham, Bolton, and Manchester; from scarlet fever in Sunderland; from whooping-cough in Bristol, Cardiff, Preston, Halifax, and Sunderland, and from "fever" in Preston. The 111 deaths from diphtheria included 49 in London, 10 in Leeds, eight in West Ham, seven in Sheffield, six in Birmingham, six in Liverpool, and four in Leicester. No fatal case of small-pox was registered last week in any of the 33 large towns, and no small-pox patients were under treatment last week in any of the Metropolitan Asylums Hospitals The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Feb. 11th, was 2642, against numbers declining from 2939 to 2665 at the end of the six preceding weeks; 253 new cases were admitted during last week, against 249, 220, and 265 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 266 and 348 in the two preceding weeks, further rose last week to 481, and were 19 above the corrected average The causes of 77, or 1·6 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Salford, Bradford, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Liverpool, Blackburn, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 21 3 to 28 4 per 1000, further rose to 31·2 during the week ending Feb. 11th, and exceeded by as much as 9 3 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 18 6 in Perth and 24 2 in Leith to 35 0 in Glasgow and 39 9 in Paisley. The 951 deaths in these towns included 37 which were referred to whooping-cough, 22 to measles, 19 to diarrhœa, nine to diphtheria, eight to "fever," and six to scarlet fever. In all, 101 deaths resulted from these principal zymotic diseases, against 78 and 95 in the two preceding weeks. These 101 deaths were equal to an annual rate of 3 3 per 1000, which was 1·5 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping cough, which had been 30 and 43 in the two preceding weeks, declined to 37 last week, of which 15 occurred in Glasgow, seven in Edinburgh, five in Dundee, and five in Leith. The deaths referred to measles, which had been 15 and 16 in the two preceding weeks, further rose to 22 last week, of which eight were recorded in Aberdeen, six in Glasgow, and four in Edinburgh. The 9 fatal cases of diphtheria exceeded by two the number in the preceding week, and included four in Edinburgh and three in Glasgow. The eight deaths referred to different forms of "fever" considerably exceeded the numbers recorded in recent weeks and included four in Glasgow and two in Paisley. Of the six fatal cases of scarlet fever three occurred in Glasgow and two in Aberdeen. The deaths from diseases of the respiratory organs in these towns, which had been 161 and 282 in the two preceding weeks, further rose to 346 last week, and were as many as 220 above the number in the corresponding period of last year. The causes of 38, or four per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24 9 and 31 8 per 1000 in the two preceding weeks, declined to 31 6 during the week ending Feb. 11th. During the past four weeks the death-rate in the city has averaged 29 2 per 1000, the rate during the same period being 18 8 in London and 24 6 in Edinburgh. The 212 deaths registered in Dublin during the week under notice were within two of the number in the previous week, and included eight which were referred to the principal zymotic diseases, against 11 and 10 in the two preceding weeks; of these, four resulted from "fever," two from whooping-cough, one from scarlet fever, one from diphtheria, and not one either from small-pox, measles, or diarrhœa. These eight deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 1 8 in London and 3 7 in Edinburgh. The deaths referred to different forms of "fever," which had been five and one in the two preceding weeks, rose again to four last week. The fatal cases of whooping-cough, which had been five and three in the two preceding weeks, further declined to two last week. The mortality from scarlet fever also showed a decline from that recorded in the preceding week. The 212 deaths in Dublin last week included 37 of infants under one year of age and 59 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the numbers recorded in the preceding week. Six inquest cases and four deaths from violence were registered; and 90, or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING 1898.

COMPLETE statistics relating to sickness and mortality during the year 1898 in each of the 43 sanitary areas of London are summarised in the accompanying table. The mortality [illegible] relate to the deaths of persons actually belonging [illegible] areas, and are the result of a com[illegible] hs occurring in the [illegible] in [illegible] which [illegible]

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING THE YEAR 1898.

(Specially compiled for THE LANCET.)

SANITARY AREAS.	Estimated population in the middle of 1898.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.

712 cases of membranous croup.

† Including deaths from membranous croup.

the notified cases of infectious diseases in London during 1898, it appears that the proportion of persons reported to be suffering from one or other of the nine diseases in the accompanying table was equal to 8·3 per 1000 of the population, estimated at 4,504,766 persons in the middle of the year. In the three preceding years the rates were 9·5, 11·1, and 10·2 per 1000 respectively. Among the various sanitary areas the lowest rates were 3·2 in St. Martin-in-the-Fields, 4·5 in St. James Westminster, 4·9 in Strand, 5·2 in St. George Hanover Square, 5·3 in St. Giles, and 5·7 in City of London; the highest rates were 10·8 in Clerkenwell, 10·9 in Newington, 11·1 in Hackney and in Battersea, 11·2 in St. George Southwark, 11·3 in St. Luke, and 11·9 in Fulham. The prevalence of small-pox in London showed a further marked decline during 1898, the new cases notified being only 32, against 2813, 1192, 979, 225, and 104 in the five preceding years; of these, five belonged to Camberwell, four to Battersea, four to Poplar, three to Lee, and two each to St. Pancras, Hackney, Whitechapel, and Port of London sanitary areas. The number of small-pox patients admitted into the Metropolitan Asylums Hospitals during 1898 did not exceed five, and no case remained under treatment at the close of the year. The prevalence of scarlet fever in London during 1898 showed a marked further decline, the number of cases notified being 16,894, against 25,647 and 22,850 in the two preceding years. This disease was proportionally most prevalent in Fulham, Clerkenwell, St. George Southwark, Newington, St. Olave Southwark, Bermondsey, and Plumstead sanitary areas. During the year under notice 12,480 scarlet fever patients were admitted into the Metropolitan Asylums Hospitals, against 11,271, 15,982, and 15,256 in the three preceding years; the number of cases under treatment, which had been 3506 at the beginning of the year, was 2883 at the end of December last. Diphtheria also showed a decreased prevalence during 1898, the cases notified being 11,855, against 11,223, 13,808, and 13,192 in the three preceding years. This disease showed the highest proportional prevalence in Fulham, Hackney, Holborn, Clerkenwell, St. Luke, St. Saviour Southwark, St. George Southwark, Battersea, and Lee sanitary areas. The Metropolitan Asylums Hospitals contained 1065 diphtheria patients at the beginning of 1898; 7390 cases were admitted during the year, and 1239 remained under treatment at the end of December last. The prevalence of enteric fever in London during the year under notice almost corresponded with that recorded in 1897, 3024 cases being notified, against 3103 in the preceding year; among the various sanitary areas this disease was proportionally most prevalent in Westminster, St. Pancras, Hackney, St. Martin-in-the-Fields, St. George-in-the-East, Poplar, and Greenwich. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during 1898 was 1116, against 661, 600, and 939 in the three preceding years, and 255 cases remained under treatment at the end of December last. Erysipelas showed the highest proportional prevalence in St. Giles, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, St. Olave Southwark, and Rotherhithe sanitary areas. The 247 notified cases of puerperal fever showed a further slight decline from the numbers recorded in the two preceding years; 20 belonged to Wandsworth, 19 to Islington, 18 to St. Pancras, 14 to Hackney, 14 to Lambeth, 11 to Kensington, 11 to Newington, and 11 to Camberwell sanitary areas.

During the year under notice the deaths of 82,037 persons belonging to London were registered, equal to a rate of 18·3 per 1000, against 19·4, 18·2, and 17·7 in the three preceding years, 1895-6-7. This rate was 1·0 per 1000 below the average rate in the 10 preceding years, 1888-97. In the various sanitary areas the lowest death-rates were 11·7 in Hampstead, 13·2 in St George Hanover-square, 13·7 in Stoke Newington, 14·4 in Wandsworth, 14·9 in Lee, and 15·3 in Lewisham (excluding Penge); the highest rates were 23·6 in St. Saviour Southwark, 23·8 in Limehouse, 24·4 in St. George Southwark, 24·8 in St. George-in-the-East, 24·9 in Holborn, and 25·7 in St. Luke. Taking the five groups of sanitary areas the rate of mortality during 1898 was equal to 16·9 in the north, 17·0 in the west, 17·7 in the south, 21·7 in the east, and 22·1 in the central districts. To the principal zymotic diseases 12,482 deaths were referred during the year under notice; one resulted from small-pox, 3069 from measles, 581 from scarlet fever, 1756 from diphtheria, 2157 from whooping-cough, three from typhus, 554 from enteric fever, nine from simple and ill-defined forms of fever, and 4352 from diarrhœa. These 12,482 deaths were equal to an annual rate of 2·77 per 1000, against 2·62, 3·11, and 2·57 in the three preceding years. Among the various sanitary areas the zymotic death-rates ranged from 0·88 in St. Martin-in-the-Fields, 1·29 in St. George Hanover-square, 1·40 in Hampstead, 1·51 in St. James Westminster, 1·56 in Stoke Newington, and 1·76 in Strand, to 3·90 in Bethnal Green, 3·95 in Shoreditch, 3·99 in St. George Southwark, 4·04 in St. Luke, 4·13 in Woolwich, and 4·26 in Limehouse. Only one fatal case of small-pox was registered in London during the year under notice, the corrected average number in the 10 preceding years being 44; this case belonged to St. George Hanover-square sanitary area. The 3069 deaths referred to measles were 301 above the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Hammersmith, Chelsea, St. Margaret Westminster, Islington, Holborn, Bethnal Green, Limehouse, and Woolwich. The 581 fatal cases of scarlet fever were as many as 435 below the corrected average number; this disease was proportionally most fatal in Fulham, St. Pancras, St. Luke, St. George Southwark, Bermondsey, and Rotherhithe sanitary areas. The 1756 deaths referred to diphtheria were 405 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Hackney, Clerkenwell, St. Luke, Mile End Old Town, St. Saviour Southwark, St. George Southwark, Newington, and Battersea. The 2157 fatal cases of whooping-cough were 364 below the corrected average number; this disease was proportionally most fatal in St. Margaret Westminster, Shoreditch, Bethnal Green, St. George-in-the-East, Limehouse, Poplar, and St. Olave Southwark sanitary areas. The three deaths from typhus included two in Kensington and one in Islington sanitary areas. The 554 fatal cases of enteric fever were slightly below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. Pancras, Hackney, Strand, City of London, Greenwich, and Woolwich. The 4352 deaths from diarrhœa were as many as 1354 above the corrected average number; among the various sanitary areas this disease was proportionately most fatal in Fulham, Clerkenwell, St. Luke, Shoreditch, Limehouse, Poplar, St. George Southwark, and Newington. In conclusion, it may be stated that the mortality in London during 1898 from these principal zymotic diseases was about 3 per cent. above the average, owing to the excessive fatality of summer diarrhœa.

Infant mortality in London last year, measured by the proportion of deaths under one year of age to registered births, was equal to 166 per 1000, a higher rate than in any of the 10 preceding years, during which period the rate averaged 155 per 1000. The rates of infant mortality in the various sanitary areas ranged from 108 in Stoke Newington, 120 in St. George Hanover-square, 125 in Hampstead, 128 in City of London, 132 in Marylebone and in St. Olave Southwark, and 137 in St. Giles, to 191 in Poplar, 195 in St. George-in-the-East, 196 in Clerkenwell and in Shoreditch, 208 in Limehouse, 211 in St. Saviour Southwark, and 221 in Holborn.

THE SERVICES.

Royal Navy Medical Service.

Fleet Surgeon Alfred Henry Miller has been placed on the Retired List at his own request.

The following appointments have been made:—Fleet Surgeon Thomas E. H. Williams to the *Defiance*. Staff Surgeon Walter G. Axford to the *Pylades*. Surgeons: Robert H. Mornement to the *Vivid*, for disposal; Harold Huskinson to the *Boscawen*, for the *Agincourt;* Richard F. Clark to the *Niobe;* H. O. Whiteside to the *Pembroke;* C. C. Macmillan to the *Wildfire;* and George Gibson to the *Tamar*.

Royal Army Medical Corps.

The under-mentioned Captains to be Majors, dated Feb. 5th, 1899:—William J. Trotter, Frederick J. Morgan, William H. Horrocks, Charles H. Hale, D.S.O., Hugh O. Thurston, Bertal H. Scott, Walter C. Poole, Oliver R. A. Julian, George Raymond, Eustace A. Burnside, Thomas McCulloch, Alfred B. Hinde, Alexander Y. Reily, John W. Cockerill, John Ritchie, Harry St. George S. Hore, Stuart Macdonald, Alexander O. C. Watson, Edward W. Gray, David Stiell, Lawrence E. A. Salmon, George A. Wade, James Minniece, Maurice P. C. Holt, William L. Gray, Edward G. Browne, James C. Morgan, Herbert I. Pocock, George Hilliard, C.M.G., Charles R. Elliott, Charles A. Young, John W. Bullen, James C. Weir, Benjamin J. Inniss, Robert C. Thacker, Stephen F. Clark, and Edward M. Hassard.

Major C. H. Burtchaell proceeds to Woolwich for duty. Captain G. S. Crawford has arrived in Dublin for duty. Lieutenant A. B. MacCarthy proceeds from Dover to Lydd to assume medical charge of troops and Station Hospital. Major H. J. Barnes has arrived in the Eastern District. Lieutenant J. G. Gill is posted to Canterbury, and Lieutenants G. C. Phipps and R. S. Roger to Western Heights, Dover, for duty.—Captains J. H. Rivers and H. A. Bray are selected for service with the Egyptian Army.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Captain L. Rogers (Bengal) are placed temporarily at the disposal of the Government of Bengal, with effect from Nov. 15th, 1898, but he will continue to officiate as Imperial Bacteriologist to the Government of India during the absence on leave of Dr. Lingard, or until further orders.

VOLUNTEER CORPS.

Royal Engineers: 1st Newcastle-on-Tyne: Surgeon-Captain T. A. Dodd to be Surgeon-Major. *Rifle:* 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Frederick Edward Apthorpe Webb to be Surgeon-Lieutenant. 3rd Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment): Reginald George Hann to be Surgeon-Lieutenant. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant J. H. H. Williams resigns his commission. 2nd Tower Hamlets: Edward Thomas McDonnell to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADE.

West London: Surgeon-Captain H. G. Thompson, 1st Volunteer Battalion the Royal Fusiliers, to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade.

ROYAL ARMY MEDICAL CORPS EXAMINATION.

The following is a list of the successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London:—

Names.	Marks.	Names.	Marks.
G. G. Delap	2393	C. C. Murison	2052
F. Warren	2388	H. B. Onraet	2047
R. A. Cunningham ...	2385	P. H. Falkner...	2043
V. J. Crawford	2384	H. F. Hart	2025
F. J. Palmer	2375	L. F. F. Winslow	2016
O. Challis	2360	H. H. Norman	1971
H. Simson	2316	A. Chopping	1935
T. G. N. Stokes	2282	J. J. W. Prescott	1930
S. G. Butler	2151	O. W. A. Elsner	1925
G. H. Irvine	2140	A. L. A. Webb	1914
W. A. Woodside	2133	E. E. Ellery	1899
W. R. Blackwell	2109	H. M. Nicholls	1846

INDIAN MEDICAL SERVICE.

The following candidates for Her Majesty's Indian Medical Service were successful at the competitive examination held in London on Feb. 3rd, 1899:—

Names.	Marks.	Names	Marks.
C. Dykes	3457	A. B. Fry	2708
W. E. McKechnie	3276	E. C. G. Maddock	2685
E. D. W. Greig	3275	A. W. Tuke	2682
D. McCay	3119	F. C. Lewis	2574
J. J. Urwin	3069	M. W. Manuk	2552
W. F. Harvey	3037	W. H. Tucker	2432
H. D. Peile	2990	C. S. Lowson	2390
W. C. H. Forster	2949	J. H. L. Beaman	2369
D. H. F. Cowin	2927	W. H. Dickinson	2295

INCREASE OF THE NAVAL MEDICAL DEPARTMENT.

The *Army and Navy Gazette* of Feb. 11th announces that the Naval Medical Department is to be largely increased in consequence of the additional requirements of an increased fleet. 50 officers are to be added progressively to the list, including nine of the senior grades. The establishments on the Mediterranean and China stations may, our service contemporary thinks, be afforded a larger professional staff. In connexion with this subject of the increase which has been made to the strength of the British navy of late years it may be mentioned that great activity has been and is still being displayed by the French at Toulon in the arming of ironclads and the construction of cruisers and torpedo-boats. It is therefore probable that, under these circumstances, the strength of the British fleet in the Mediterranean will not, at any rate, be decreased.

THE FINANCES OF INDIA.

Notwithstanding the very trying circumstances to which our Indian Empire has been exposed and under which it has been labouring of late years—namely, plague, famine, and a big war on the frontier—the finances of the country are sound and a considerable surplus may, we learn, be expected in the forthcoming Indian Budget. The Military and Public Works Departments have large unexpected balances from their estimated cost and the railways are stated to have done remarkably well during the year. Money, it may be said, measures everything; and while the state of the Indian exchequer speaks well for the way in which that country is administered it holds out the hope that progress may continue to be made in the improvement of the public health and the prosecution of sanitary works in India.

THE TRANSPORT OF SICK SOLDIERS.

A correspondent in the *Morning Post* of Feb. 14th severely takes to task the Army Medical Service for incompetency in dealing with sick troops and in particular characterises the medical arrangements made for the Salisbury Plain manœuvres as "mediæval in type." We are quite aware of the fact that there are many matters connected with the Army medical arrangements that stand in need of reform, but it is the War Office who are to blame and not the Medical Department, who are hampered by it. We do not fear that the public will be misled by the invective of our contemporary's correspondent who takes shelter under anonymity, but it is only fair to the Army Medical Service that we should call attention to the matter.

HONORARY SURGEONS TO THE VICEROY OF INDIA.

Surgeon-General R. Harvey, C.B., D.S.O., I.M.S., Surgeon-General W. S. M. Price, A.M.S., Colonel D. O'C. Raye, I.M.S., Colonel D. Sinclair, C.S.I., I.M.S., Colonel W. P. Warburton, C.S.I., I.M.S., Lieutenant-Colonel G. D. Bourke, R.A.M.C., Lieutenant-Colonel A. J. Willcocks, I.M.S., and Lieutenant-Colonel P. H. Browne, C.I.E., I.M.S., have been appointed honorary surgeons to the Viceroy of India.

Correspondence.

"Audi alteram partem."

"REGINA v. REICHARDT."

To the Editors of THE LANCET.

SIRS,—I will not take up your space by discussing with Mr. Sers "what constitutes insanity." My intention was to point out that, admitting the poor lady who drowned herself to have been temporarily insane, the Lunacy Act was, I suppose, framed that the insane might have every possible advantage in helping them to *recover.* But if every case of temporary insanity treated away from home must be put under certificates before it is treated because this is the law, then for hundreds of cases, thousands of cases, not the best for, but the very worst against, their recovery is done. The rigid letter of the law may say you must do this or that, but you cannot *treat* disease by Act of Parliament, and in the *administration* of the Act considerable latitude ought to be allowed in adapting it to the treatment of disease. I cannot conceive how, when three qualified men of good reputation have separately decided that A or B is not a case to be placed under certificate, the law can step in and say it is. It is an attempt on the part of the law to go beyond its domain and to treat disease, and that attempt ought to be resisted in all just cases. I trust that the endeavour to improve the Act in this respect that Dr. Rayner speaks of may soon be an accomplished fact, for a prosecution such as that of Regina v. Reichardt seems to me a positive scandal, although I am of course quite ready to admit that the Commissioners only acted as they considered their duty compelled them.

I am, Sirs, yours faithfully,
DR. JAMES F. GOODHART.

Feb. 14th, 1899.

THE SURGICAL AID SOCIETY AND ITS METHODS.

To the Editors of THE LANCET.

SIRS,—Most surgeons are under the impression that this body has for its object the providing of surgical apparatus to the poor, chiefly hospital patients, on the recommendation or certificate of a surgeon only as stated in their advertisements.

The following incident which has recently occurred and which I am led to believe is not an isolated case shows how grievously their confidence may be misplaced and requires an explanation from the society. A little child, under my care at the Children's Hospital, Shadwell, was recommended by me to get an apparatus and the requisite number of letters was collected. A lady interested in the child's welfare and who originally asked me to see her took her up to Salisbury-square and was there told by an elderly official that the doctor had ordered quite the wrong thing. She was advised to see another surgeon and sent away with a printed paper bearing the name of a surgeon to the National Orthopædic Hospital, Great Portland-street, with the cheering prospect of getting much more efficient treatment. Fortunately she refused to be cajoled by any such seductive offer and returned to me with the document. The first question I would ask is—Does the society or does it not provide apparatus as they state on the recommendation of any surgeon? If they do not then let the profession openly know that it is provided only subject to the approval of a specialist. What is absolutely indefensible is the flagrant attempt to divert patients from one surgeon to another, to say nothing of destroying the patient's confidence by the delicate suggestion of his incompetence. As this is a matter of great importance to hospital surgeons I trust you may find space for it in your valuable journal.

I am, Sirs, yours faithfully,
HY. BETHAM ROBINSON.
Upper Wimpole-street, W., Feb. 13th, 1899.

MEDICAL AID ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to ask your readers for copies of reports of medical aid associations?

I am, Sirs, yours faithfully,
T. GARRETT HORDER.
32, Windsor-place, Cardiff, Feb 7th, 1899.

INSTRUCTION IN ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—Is it not high time that the administration of anæsthetics was systematically taught in our medical schools? At present a medical man as soon as he is qualified is supposed to be able to administer anæsthetics, although he has probably never received systematic instruction in this subject. This is not fair either to the medical man or to the patient I should like to offer the following suggestions: 1. There should be attached to all hospitals in connexion with medical schools an honorary anæsthetist who should rank with the visiting staff and who should instruct the medical students, both practically and by lectures, in the administration of anæsthetics. 2. The General Medical Council should make this instruction compulsory. 3. No hospital should appoint as resident anyone who had not received such instruction.

I am, Sirs, yours faithfully,
Leeds, Feb. 7th, 1899. CHARLES POWELL WHITE.

THE DUTY OF THE PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—The public vaccinator of the —— district appears to be sending out notices to the parents of unvaccinated children *irrespective of their position*, stating that he intends to call on a certain date to "offer to vaccinate" their child. This is followed in due course by the visit and a threat that the visit will be repeated at intervals until the vaccination is permitted. At least, this was done to one of my patients, the vaccination of whose child was postponed by me on account of sickness. I consider the action of the public vaccinator, to say the least, ungentlemanly and presumptuous and I can assure him, firstly, that the child in question will not be vaccinated until I consider it in a proper state of health, and secondly, that when the child is vaccinated it will not be by the public vaccinator of ——.

But what I desire to ask you, Sirs, is whether this procedure is sanctioned by the Local Government Board. I may add that the father of the child is in a lucrative business, has never had any children vaccinated at the expense of the ratepayers, and was greatly astonished at the public vaccinator's visit. I enclose the notice sent.

I am, Sirs, your obedient servant,
Feb. 12th, 1899. L.R.C.P., M.R.C.S.

THE NEW VACCINATION ACT: "COMFORT" FROM THE LOCAL GOVERNMENT BOARD.

To the Editors of THE LANCET.

SIRS,—Early in December I asked my guardians to come to an agreement *re* the new vaccination fees. Their reply was a notification of a "resolution" (received on Dec. 31st) that they would pay the minimum fees. I then put it to the Local Government Board that the fault was not mine that no agreement had been arrived at and asked whether, if I refused the guardians' fees, the guardians could summarily dismiss me. I also asked whether a mere "resolution" of the guardians constituted an "agreement" as required by Article 4 of the General Order. The Local Government Board replies are as follows (taking the last question first): "*A resolution of the guardians does not constitute an 'agreement.'*" One would think from this that the Local Government Board would at once itself determine the fees to be paid in accordance with its own "General Order." But not so. I am informed that notwithstanding the neglect of the guardians to carry out the Order it is still within their power to terminate my contract should I fail to comply with their "resolution." The "comforting" part then comes: that in the event of the guardians dismissing me I shall be entitled to payment for work done *up to the time of the expiration of my notice to quit.*

When it is remembered that the *vaccination officer* cannot be dismissed by the guardians a feeling of surprise creeps over me.

I am, Sirs, yours faithfully,
Feb. 8th, 1899. X.

"THE EXPERIENCES OF A PUBLIC VACCINATOR."

To the Editors of THE LANCET.

SIRS,—I am with many of my fellow public vaccinators quite able to confirm the statement of your correspondent as to the large amount of work and the small profit attendant on that work undertaken by him in his duties under this new Vaccination Act. But what he leaves unsaid is the loss of self-respect and mental *degradation incurred* in performing these duties. It is bad enough in the slums where one hears oneself announced as "a bloke as wants to vaccinate the babby" and a dirty slut, called the lady, comes down and declines one's offer in choice slang meant to be as offensive as can be produced; it is still worse at the villa where the maid leaves one on the steps while she puts the chain up and goes to consult her missus. After hearing interjections such as "The idea!" "What next!" the girl returns with "Please missus says she isn't at home; she doesn't intend to have it done at all, and it shall be done by her own doctor." In the cloud of one's mind caused by all these contradictions one finds oneself outside and to seek the interior of one's brougham to carry one to fresh insults. Two contiguous houses were of one mind not to open the door to me, and though I could feel the vibration of people moving about and my coachman could see the inmates through the glass above the door ascending and descending no response was made to my four visits on four separate weeks, and the only effect obtained was to produce merriment in the neighbours who looked and grinned at their windows. Cannot a new *modus vivendi et operandi* be agreed upon? Cannot the vaccination officer first obtain consent of these people and then carry the names of these consenting ones to the public vaccinator and so spare him so much fruitless toil, or cannot vaccination stations be restored where he may only meet those who wish for his services? This present domiciliary work cannot continue if worked on its present lines.

I am, Sirs, yours faithfully,

Feb. 11th, 1899. "P. V."

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—The press, both medical and non-medical, has welcomed with considerable cordiality the formation of this society and, as far as I am aware, nothing but goodwill has been exhibited towards it by the medical profession. It should prove a success.

Whilst sympathising deeply with the objects of the Association and wishing a happy issue to its endeavours to prevent tuberculosis of all kinds, may I be permitted to point out one or two things in connexion with it which are in my opinion open to criticism? In the first place, on looking over the list of names of the gentlemen forming the organising committee one cannot but be struck with its want of representative character and this becomes more evident when one subjects the list to more careful analysis. One finds, for example, that of the special hospitals in the metropolis for the treatment of consumption, of which there are five with about 60 physicians in their service, only one has any representation upon the said committee, by a consulting physician and a junior physician; the others are totally unrepresented. Again, of the general hospitals in London, the four largest, for example, as far as I can make out, do not contribute any names to the list. Thirdly, the provincial hospitals for consumption, such as Bournemouth, Torquay, Ventnor, and the like have only one representative; Edinburgh and Belfast none.

As a matter of curiosity I have tried to find in the Medical Directory which of the 21 members of the committee are or have been connected with special hospitals for consumption in this country but have only succeeded in the case of five or six. Do not think that I have anything whatever to say against the names on the committee except that they are to some extent unrepresentative, or yet that it is my wish to demonstrate that those who have had practical experience in *treating* consumption on a large scale are any more able to help in the *prevention* of the disease than those who are not. All I desire to indicate is that it might have been more satisfactory if the representative principle had been taken into consideration when the committee was formed. I am afraid that this cannot now be rectified, as the *addition of further* names would only accentuate their absence in the first instance.

The other point to which I think exception may be taken is the advertisement of the Association by detailed reports of meetings held under its auspices in the lay press. This, I think, has two disadvantages—that statements divorced from their context are often made specially prominent by the reporters or editors who, of course, cannot be expected to take much interest in medical subjects except so far as they may be readable by their clients, and that certain statements are sometimes distinctly misleading. Thus some weeks ago I saw in one of the daily papers a statement with reference to heredity as predisposing to consumption (based upon some remark of a speaker at one of the tuberculosis-prevention meetings in the country) which might prove very mischievous. Another disadvantage in connexion with such a method of pushing the interests of the society, is that it is open to the suspicion of being a bid on the part of the prominent organisers of such meetings for publicity or public favour. We are fully aware that this is not the case, but it is certainly a fact that the names of the speakers at such public meetings *do* "catch on" with the general public when prominently brought into notice by the daily press.

I am aware that answer might be made that it is publicity which is wanted to make the work of the Association effective and this is perfectly true. Publicity certainly for the excellent aims and objects of the association, but publicity for these alone.

I am, Sirs, yours faithfully,

AN ONLOOKER.

Feb. 6th, 1899.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Commission.—The Nature of the Evidence.—The Progress of the Epidemic.—More Curative Serum.

AT the second sitting of the Plague Commission at Lahore Captain Wilkinson was examined. He cited one instance to show that clothes appeared to be the medium of infection apart from the person. In one village he recorded that the victims were rats only, whilst no human being was attacked. He knew of no positive proof that rats communicated the disease to human beings. At the last sitting Major Skinner gave evidence. He still disputed the theory that the cases in the Shropshire regiment in Barrackpore and Howrah were cases of real plague, but while he detailed certain symptoms and the results of his microscopic examinations his arguments were not conclusive.

The Plague Commission commenced to take evidence at Karachi on Jan. 23rd. Mr. Giles, the acting Commissioner for Sind, was examined and detailed the history of plague in Karachi and the measures which had been taken. He expressed his opinions on certain means by which he thought plague was spread, but no scientific evidence of these means was given. Similar opinions have been expressed at other places, but being wholly unaccompanied by any evidence of scientific value they remain merely the individual opinions of their exponents. Lieutenant-Colonel McCloghry, the civil surgeon, attributed the second outbreak to the migration of rats and to people moving from the infected to the uninfected quarters. Contagion was due more to rats than to human agency. He thought that rats generally contaminated the dwellings with their excreta. He cited a case where human agency was perfectly excluded, tending to show that contagion was entirely due to dead rats. Other witnesses, military and civilian, were also examined and their opinions were expressed in detail upon the value of disinfection and other sanitary measures. Similar evidence has been taken at other places. Why time and money are wasted in getting such evidence as this seems to me to be incomprehensible. Their opinions are *only opinions* and are not sufficiently supported by facts. Protests have been uttered against the examination of a hakim (a native quack doctor) upon his experiences of plague in Garhshanker. He was allowed to give his views freely on many medical questions, but his evidence was of no real value. To recognise such men—to let it be known all over the country that a scientific board of savants is apparently seeking their opinions—is to mislead the lowest and most uneducated classes of the native communities. It gives these men a status at once and therefore degrades the *men* who have qualified after training in the Indian universities. If qualified native practitioners were not available as witnesses hospital assistants who have had medical training might have been summoned. It is advisable to compel the hakims *and* vaids under pain of penalty to *report all cases of infectious disease*, and in the absence of a Medical Act and any system of medical registration this does not add *to* their status, but to accept their medical evidence is liable to misinterpretation and should be done with caution.

The mortality from all causes in Bombay city during the past week was 1449, as against 1239 in the week preceding—an increase of 210. The *average* weekly mortality for Bombay is about 500, so that over 900 deaths have to be accounted for. Out of this only 456 deaths from plague have been recorded and as there is no other epidemic to account for the increased mortality this shows *how* absurdly inaccurate the returns are. The Presidency plague returns taken on a whole are more favourable, although 343 villages still remain infected. Last week 360 were declared to be infected. Another source of confusion exists in the different dates to which the returns are compiled. The Presidency returns are made up from Friday to Friday, the local hospital reports run from Saturday to Saturday, and the municipal health officers returns go from Tuesday to Tuesday. The weekly returns are consequently all different.

Notwithstanding the great increase of deaths from plague in Bombay city inoculation is proceeding very *slowly*. Only 388 inoculations appear to have been done for the week ending Jan. 20th and these chiefly among low caste Hindus. Last year when the authorities *could* have offered inoculation in place of detention and segregation they had a powerful means of encouraging this form of protection. Now that detention and passes have been abolished and the plague regulations do not frighten the people there is no leverage of assistance which can be given to inoculation. In Bombay large numbers of practitioners have been appointed to perform inoculation free of charge. In the Mofussil a charge of two annas was made—it then appeared a privilege—and the people flocked in thousands to be inoculated.

I understand that in addition to the supply of serum shortly to be made available from the animals which have been prepared during the past few months after the manner of Lustig there has arrived a new supply of curative serum from Paris prepared by a different process. The cases admitted into the Municipal Fever Hospital are reported to be of a very virulent type so that the present seems a particularly favourable time to test the value of any new methods. I must again caution the profession against accepting any future statistics unless they have been based on consecutive admissions to hospital.

Jan. 25th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Northern Hospital.

DURING the year 1898 there were attended to at the Liverpool Northern Hospital 1530 in-patients and 7466 out-patients, involving 23,414 attendances. The ordinary expenditure was £7284 7*s.* 10*d.*, being a slight decrease on the expenditure of the previous year. There is a balance of £2925 2*s* 8*d.* due to the bankers of the hospital. The receipts from all sources (including £1560 from the Hospital Sunday and Saturday Fund and £1819 16*s.* 3*d.* from subscriptions) amounted to £5528 13*s.* 11*d.* The financial condition of the charity is the subject of anxious consideration to the treasurer in view of the approaching completion of the new building, which, it is needless to say, will involve a large outlay.

Liverpool Select Vestry: the Proposed New Workhouse Hospital: Conference on Tuberculosis.

The special sub committee appointed by the Liverpool Select Vestry to consider the plans for the proposed new hospital at Highfield reported that the estimated total cost of the building and equipment was £105,353. The price of the land was £10,000. Accommodation would be provided in the new hospital for 280 infirm poor who were now located in the attic wards of the Brownlow Hill Workhouse which had been condemned by the Local Government Board for obvious reasons. The difficulties in removing the inmates of these wards in case of fire would be very great and the subject had been a matter of friction between the Select Vestry and the Local Government Board for the last ten years. The cost worked out to £210 per bed, which does not appear to be extravagant. The three poor-law authorities comprising the Select Vestry, the West Derby Board of Guardians, and the Toxteth Board of Guardians have agreed to meet together to consider the desirability of joint action in regard to the new method of treatment of patients in the workhouse hospitals suffering from tuberculosis, of whom there are about 80 in Brownlow Hill Workhouse. West Derby has rather less and Toxteth has a still smaller number. It is hoped that through the conference some uniform arrangement will be arrived at for the treatment of tuberculosis in the incipient stage, and the prevention of infection in others.

Donations to Hospitals.

The late Mr. William Taylor of Southport has bequeathed £500 to the St. Paul's Eye Hospital, Liverpool. Mr. Samuel Smith, M.P., has given £100 to the Children's Infirmary, Liverpool, and also £100 to the New Central Hospital at Liscard, in memory of his son, Mr. James Gordon Smith, who died recently from typhoid fever.

Workmen's Compensation Act: House Surgeon's Fees.

The committee of the representatives of the Liverpool hospitals appointed to consider the question of fees for certificates given by house surgeons under the provisions of the Workmen's Compensation Act have recommended that house surgeons be entitled to charge one guinea for each report to insurance companies and employers of labour.

Treatment of Tropical Diseases.

At the annual meeting of the Royal Southern Hospital, held at the town hall on Feb. 13th, the Lord Mayor who presided said that it was one of the first obligations of the port to relieve the sufferings of patients who had contracted disease in West Africa, especially in connexion with the trade and commerce of Liverpool, and that the Royal Southern Hospital had been selected for this purpose. Mr. William Adamson (the President) afterwards stated that last year Mr. A. L. Jones, a member of the hospital committee, generously offered £350 towards the establishment of a school for the study of tropical diseases; a large ward has been appropriated for the reception of such diseases, an experienced clinical demonstrator has been appointed, and advertisements have been issued for a lecturer. The school expenses will be administered by an independent committee and from a separate fund.

Feb. 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

IT has been determined to take steps to promote the establishment of a permanent memorial of the late Professor Coats and of his valued work and influence in the University. The committee which has been appointed to secure this end includes the names of the Very Reverend Principal Storey, Sir William Gairdner, K.C.B., Dr. James Finlayson, Dr. Lindsay Steven, Dr. Donald Fraser, and Dr. David Newman (honorary secretary).—At a meeting of the University Court on Feb. 9th it was announced that the late Mr. William Gardiner, M.D. Glasg., of Ashton-under-Lyne had bequeathed to the University the sum of £1000 for the purpose of founding a bursary in the Faculty of Medicine.—At the same meeting Sir William Gairdner intimated his desire to resign his position on the Board of Curators, in whom the patronage of the chair of Pathology is vested, and Professor McKendrick was appointed in his place.—The names of two more gentlemen are mentioned in connexion with the vacant assessorship of the University Court—viz., those of Sir James Bell and Mr. W. R. Copland, C.E. Sir James Bell was formerly member of the Court in virtue of his position as Lord Provost of the city and Mr. Copland has for some years been convener of the business committee of the University Council.

Aberdeen Sick Children's Hospital.

The number of cases treated in the wards of the Aberdeen Royal Hospital for Sick Children in 1898 was 889, the average duration of treatment was 32·1 days, and the average number of beds occupied daily was 80·8. The ordinary revenue was over £3572, the average annual expenditure per bed occupied was £43 2*s.* 5½*d.*, and the average daily expenditure per patient was 2*s.* 4·351*d.* The ordinary income amounted to more than £2093, and the extraordinary income (including legacies, donations to building fund, contribution from Queen's Diamond Jubilee Fund, and proceeds of bazaar) was over £4230. The special fund for the erection of a nurses' and servants' home has been closed. During the summer 48 children were received at the Eidda Convalescent Home, Culter, their stay varying from four to 20 weeks.

Typhus Fever in Aberdeen.

An outbreak of typhus fever has taken place in the Footdee district, Aberdeen, four cases having been removed to hospital during the week ended Feb. 11th. Of late years typhus fever has been almost unknown in the city.

Feb. 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal College of Physicians of Ireland and Dr. Clifford Allbutt.

AT a special meeting of the Royal College of Physicians of Ireland held on Feb. 14th, 1899, the Honorary Fellowship of the College was conferred on Dr. T. Clifford Allbutt, Regius Professor of Physic in Cambridge University. In admitting the new Honorary Fellow the President *said that in conferring upon Dr. Clifford Allbutt* the highest dignity which it was in their power to bestow the Fellows felt that they were doing honour to themselves, but above all to that ancient College of which they were so proud and the prestige and good name of which they so jealously guarded.

Dublin University.

A meeting of the Senate of the University of Dublin took place on Feb. 14th in the examination hall of Trinity College, for the purpose of conferring degrees. The University Caput—consisting of Mr. Justice Madden (Vice-Chancellor), Rev. Dr. Salmon (Provost), and Mr. Cathcart (senior master non-regent)—presided. The attendance included Fellows and professors of Trinity College, other members of Senate, and a number of ladies who were accommodated with seats on the daïs. Two degrees *honoris causâ* were conferred—one on Dr. Thomas Clifford Allbutt, Regius Professor of Physic in Cambridge University, and the other on Sir Thomas Moffett, formerly President of the Queen's College, Galway.

Irish Medical Association.

The Council of the Irish Medical Association has convened a public meeting of the profession to be held by permission in the Royal College of Surgeons, Dublin, on Thursday, March 2nd, 1899, at 4 o'clock P.M., under the chairmanship of Sir Thornley Stoker, M.D. R.U.I., President of the Association, for the purpose of promoting the reform of the grievances of the Irish Poor-law Medical Service.

The Royal Victoria Eye and Ear Hospital.

The second annual general meeting of the Royal Victoria Eye and Ear Hospital took place on Feb. 14th at the Mansion House, Dublin. The Right Hon. Viscount Monck presided.

Queen's College, Belfast.

At a meeting of the corporate body of Queen's College, Belfast, held in the council chamber on Feb. 10th, for the purpose of considering the present position of the Irish University question (the president occupying the chair) the following resolutions were passed:—

1. That in our opinion the present provision for university education in Ireland is unsatisfactory.
2. That it is desirable that all candidates for university degrees should have attended complete courses of lectures at a recognised college or institution.
3. That in any re-settlement of the university system of Ireland it is essential that in this College provision should be made for the endowment *of new Chairs, especially those required to meet the peculiar* needs of this community, for the appointment of assistants and demonstrators, for additional laboratories, for museums of science, art, and antiquities, for more liberal additions to the library, and for facilities of research. The want of these at present seriously impairs the efficiency and lowers the status of this College as a place of learning and education.
4. That in our opinion the higher education of the North of Ireland would be admirably served by the re-establishment of the old Queen's University on its former broad non-sectarian basis, with such modifica*tions as would meet the altered circumstances of the case*, but with its seat in Belfast and with the provision of an adequate endowment.
5. We are of opinion that in the proposed new Queen's University it is essential to include Chairs of Philosophy and Modern History.
6. That copies of these resolutions be sent to his Excellency the Lord Lieutenant, the Chief Secretary, the Prime Minister, and the Leader of the House of Commons.

The importance of, and the value to be attached to, the above resolutions rest in the fact that they are the unanimous opinion of the professoriate of Queen's College, for at the meeting at which they were discussed every professor was present except two and one of these was unable to attend through indisposition. Further, they are the expression of the views of men who are all actively engaged in teaching and who thus may be regarded as experts. The question of university education is still being very fully discussed and a new turn has been given to the subject by a letter from the Roman Catholic Bishop of Down and Connor who claims that the Roman Catholics of Belfast and of the rest of his diocese must be considered in any settlement of the matter. He points out, as a conspicuous example of their generosity, that they are building at a cost of £50,000 a new hospital—the Mater Infirmorum—which when completed will afford opportunities of clinical instruction for medical students equal to those of any similar institution in the country. Accordingly the Bishop writes that "no reconstruction of the University system of education can be regarded as satisfactory or just which ignores these undoubted claims to equality in the domain of higher education." Although it is evident that there is strong opposition to Mr. Balfour's proposals it is becoming more and more clear that the present state of affairs cannot continue. The resolutions of the Queen's College professors have produced a marked effect among thinking men who naturally ask why do these authorities in educational matters who have tried patiently and faithfully to do their best under the existing *régime* declare that the present provision for university education in Ireland is unsatisfactory. The question—admittedly a difficult one—should be discussed on purely academic grounds and it is a great pity that any other element, political or sectarian, should be introduced.

The Belfast Lunatic Asylum.

From the annual report of Sir G. P. O'Farrell, the Inspector of the Board of Control, I learn that the condition of Purdysburn auxiliary asylum was quite satisfactory. Discussing the problem of how best to provide for the lunatic poor of Belfast, he recommends that provision should be made at Purdysburn for the acute and chronic classes and for the mild classes of insanity now located in the workhouse and he thinks that one portion of the estate at Purdysburn would lend itself admirably to the establishment of a colony for working epileptics. Dr. Walter Smyth has been appointed medical superintendent of County Antrim Asylum. He was formerly second assistant in the Belfast Asylum. Dr. R. A. L. Graham has been selected to fill Dr. Smyth's vacated post. There are now 994 patients on the asylum register.

The Belfast Maternity Hospital.

At the annual meeting of the subscribers of this hospital held on Feb. 7th it was reported that there were 279 intern and 166 extern patients. A committee has been appointed to make the arrangements to raise the necessary money for building a new maternity hospital and an encouraging response has already been given. The new building is to cost £1000. In the interests of the medical school and of the poor of Belfast a new maternity hospital is much needed.

Feb. 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Exhibition of 1900 and the Assistance Publique.

THE committee nominated by the Board of Trade to decide as to the admission of exhibitors in Class 112—i.e., the Assistance Publique, private charities and penitentiaries—has sent out a circular to the most important charitable bodies in France asking for their coöperation in the Exhibition of 1900. The programme drawn up by the committee groups together on the one hand charitable works of every kind, such as are both very numerous and as deal with a vast variety of subjects, and in a second group are placed those institutions concerned with penitentiary work. The Class is to be divided into five sections, as follows: (1) general exhibits, historical exhibits, and sundry legislative enactments; (2) protection of children; (3) help for adults in sickness; (4) help for the able-bodied poor, for the blind, and for deaf mutes; and (5) State pawnbroking establishments and penitentiaries. Exhibitors in Class 112 can avail themselves by special permission of the gratuitous use of sites and the administration will defray the cost of show cases, shelves, stands, and other necessaries for exhibits. The railway companies are also allowing reductions for the carriage of exhibits of 25 per cent. for the single journey and 75 per cent. for the return. By Clause 72 Section 3 of the general regulations exhibitors are invited to get together a series of historical exhibits for each section. Suggested subjects for this are the treatment of the sick in hospitals at different epochs, the care of lunatics, of the aged, of infants, together with books, papers, and drawings dealing with such matters. It will thus be seen that this portion of the Exhibition will form a most interesting temporary museum. Collectors desirous to take part in this exhibition should send in a separate application upon a special form stating plainly the description and the value put upon the objects which they lend. The administration will hold itself responsible for exhibits, but only as far as the declared value put upon them by exhibitors in accordance with the terms stated on the admission tickets.

Statistics of Paris Medical Students.

The Paris Faculty of Medicine has published a list of the number of students in medicine who gave in their names for the medical course of the past scholastic year. This is an interesting piece of information for thereby the reader is enabled to form some idea as to the effect of the recently passed university regulations as to fees and the like. It must be remembered that foreigners now only receive a doctor's degree which, although of the same scientific value as that granted to Frenchmen, yet does not permit them to practise in France unless indeed they have undergone the same preliminary examinations as Frenchmen have to pass. It was considered that this regulation would adversely affect the flow of foreign students in medicine. Their numbers, however, have not diminished. On the other hand, it is interesting to see whether the increased severity of the entrance examination has in any way diminished the rush of students into a profession at present greatly overcrowded. The result from this point of view is apparently satisfactory. In 1897 there were 5015 students entered, while in 1898 the number fell to 4495. This diminution is, however, only apparent and arises from the fact that the Faculty has struck off its roll a large number of students whose names were still on the books but who have given up trying to pass the examinations. All those who have entirely discontinued their studies for the past five years have been struck off the roll. Their numbers account exactly for the falling off mentioned above. A proof that the number of students is not falling off is given by the following figures for past years. In 1885 the Faculty examined 3856 students, 5468 in 1891, 6803 in 1893, 8346 in 1894, 8955 in 1896, 8971 in 1897, and 9429 in 1898.

The Medical Department of the Prefecture.

In accordance with a resolution of the Municipal Council passed on Dec. 28th, 1898, dealing with a scheme for the unification of the various Prefectal medical services the Prefect of the Seine has issued an order as follows for the re-organisation of such departments. Paris is divided into 11 districts, every one having its own medical man. A twelfth medical man, with the title of *médecin en chef de la préfecture*, is in charge of the whole with a salary of 6000 francs per annum. The 11 medical men under him are only paid 1200 francs per annum, but they are allowed in addition a commission on the number of visits paid or consultations held. The duties of the 11 medical men who bear the title of *médecin de la préfecture de la Seine* will be to treat patients only at their own homes or, if the patient is able, in the consulting-room. As regards municipal workmen and *octroi* officials the medical men must attend them for as long a period as may be necessary. When the regular medical man is absent through sickness or any other cause his place is to be taken by one of the *médecins adjoints* who are elected by competition. They rank according to the order of their admission and the number of vacancies which occur.

Notes on News.

M. Brouardel has been by an almost unanimous vote of the Professors and Fellows re-appointed Dean of the Paris Faculty of Medicine for a fresh period of three years.

At the meeting of the Academy of Sciences held on Jan. 30th M. Roux, the sub-director of the Pasteur Institute, was elected a titular member of the Section of Rural Economy, in succession to M. Ainé Girard, deceased. M. Roux received 41 votes, as against 14 obtained by M. Risler, the director of the Institute of Agriculture.

The buildings of the new Academy of Medicine have just been begun and the buildings of the Mont-de-Piété, which hitherto have occupied the site, have been pulled down. The plans as put forward by the architect are considered to show that the new Academy will be one of the most beautiful buildings in Paris, but it will hardly be ready by 1900.

Professor Berger, President of Section XVI. of the Exhibition, which is reserved for the class of surgical instruments, is getting together a collection of obsolete and ancient surgical instruments. He has notified various surgeons and instrument makers by circular that they are invited to send to him any examples of such instruments as may be in their possession. Anyone sending an exhibit will receive a free admission ticket for the Exhibition.

Feb. 15th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Lupus Erythematosus.

AT a recent meeting of the Vienna Dermatological Society Professor Hans von Hebra showed some cases of Lupus Erythematosus treated by a new and simple method which he has been using for some time with highly satisfactory results. The methods of treating this disease were till now based upon a removal of the diseased tissue either by mechanical or by chemical means. The treatment adopted by Professor Hebra consists in the external application of absolute alcohol to the diseased parts of the skin. A piece of surgical wool soaked in alcohol is placed against the diseased part, avoiding any rubbing of the skin. This procedure is repeated frequently (at least 10 times) daily. The more frequent the application of this wool the better the result. It seems that the beneficial effect of this treatment is due to the action of the cold produced by the evaporation of the alcohol and by the abstraction of water from the tissues. It can be seen that the blood-vessels contract and that the inflamed parts become less red and less swollen. To increase the anti-inflammatory action of the alcohol Professor Hebra adds equal parts of sulphuric ether and spirit of peppermint. He has used this treatment with much success in six cases of lupus erythematosus (five cases of the chronic discoid type and one case of the acute aggravated type of the disease). A case of 25 years' standing improved very much under this treatment. Other medical men who have tried it have also had favourable results.

Cardiac Arrhythmia.

Professor Heitler has made some very interesting observations on the production of arrhythmia of the heart in animals. In the course of a series of experiments performed at the laboratory of Professor Basch in Vienna he observed that by pricking the pericardium of a dog with needles an arrhythmic pulse is produced. When cocaine has been used locally to make the pericardium anæsthetic the mechanical stimulation of this membrane does not produce any change in the heart-beats. In a series of recent experiments Professor Heitler obtained an arrhythmic pulse by brushing the pericardium with croton oil and with sulphuric acid. The arrhythmia so produced disappears after some time, but when the irritant has been injected into the heart-muscle an arrhythmic pulse is produced which does not disappear, because in the latter case the heart-muscle becomes paralysed. By these experiments it is shown that one of the causes of arrhythmia may be a mechanical or chemical irritation of the pericardium and that this kind of arrhythmia may disappear as soon as the irritation has ceased without causing any further disorders of the heart-beats.

Infectious Diseases in Austria.

In the opening days of this year two cases of rabies in the human subject occurred at Trieste and there is an increase in the number of cases of rabies among dogs reported from Dalmatia. Outbreaks of typhoid fever were reported last week from the two Austrian seaports, Pola and Trieste, the disease being ascribed in both towns to infected oysters. At Lieben, a suburb of Prague, 20 cases of typhus exanthemicus occurred at the police barracks with three deaths in the course of last week and two cases of the same disease were notified at Leitmeritz, a town in Northern Bohemia. It must be remarked that the sanitary conditions of Prague as well as of Pola and Trieste are far from being in accordance with modern requirements and that the water-supply in these towns is extremely bad.

Feb 12th.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—An ordinary meeting of the Lodge was held at Frascati's Restaurant on Feb. 14th, Bro. Burns, W.M., being in the chair. Bro. Roberts was admitted to the third degree in Freemasonry. Bros. Lewis, Kennedy, and Hood were admitted to the second degree. Messrs. E. H. E. Stack and Sydney Cornish were initiated into Freemasonry. A vote of one guinea was made towards the maintenance of "Our Brother's Bed" in the Home for the Dying and Bros. Burns, Izard, and Coventon were respectively appointed stewards to each of the three Masonic charities, a sum of 10 guineas being voted to each list. The brethren afterwards dined together.

Obituary.

THOMAS COOKE, F.R.C.S. ENG., M.D. PARIS.

MR. THOMAS COOKE, the well-known anatomist, died suddenly on Feb. 9th in his fifty-eighth year. He was the only son of John Hawley Cooke and Jane Hawley, daughter of the Hon. Richard Hawley. He commenced his medical studies in Paris, taking his B.A. and B.Sc. in 1862 and his M.D. in 1870. During his career in Paris he held the appointments of house surgeon to the hospitals of Bicêtre, Ste. Eugénie, St. Louis, Lariboisière, and Le Midi. He was demonstrator in anatomy at the École Pratique de la Faculté de Médecine de Paris and was awarded the bronze medal by the Administration de l'Assistance Publique. In 1871 Mr. Cooke took the F.R.C.S. Eng. and in the same year was elected assistant surgeon at the Westminster Hospital, to fill the vacancy caused by an assistant surgeon becoming surgeon. After two more vacancies in the post of surgeon had been filled up Mr. Cooke became senior assistant surgeon. A vacancy for a surgeon occurring in 1875 Mr. Cooke became a candidate but Mr. Macnamara who had been a student of King's College and had recently returned from 20 years' service in India was appointed upon claims which were in many directions stronger. Mr. Cooke had acted as demonstrator of anatomy and when a vacancy occurred in the lectureship of anatomy in the Medical School Mr. Cooke became a candidate, but for reasons into which it would serve no purpose to enter now he was not elected. Mr. Cooke declared, and quite rightly, many years afterwards that the refusal to recognise his just claims compelled him to rely upon his own exertions and to develop his own private school, with which his name is so widely and favourably associated. There was no further vacancy for a surgeon until 1893, when Mr. Bond who was two years junior to Mr. Cooke was appointed, the latter not becoming a candidate; he never applied for any subsequent vacancy. Having served more than seven years Mr. Cooke became surgeon to out-patients. In 1887 an extra assistant surgeon was appointed to see out-patients on Mr. Cooke's days and some years later Mr. Cooke was by special resolution "relieved of all care of in-patients and out-patients." His name continued to appear on the list of the staff without any stated time for attendance.

In 1870 Mr. Cooke founded the widely known London School of Anatomy and Physiology which he conducted up to the time of his death. In the work which he had thus undertaken Mr. Cooke was animated continuously by the earnest desire to "provide students with a knowledge of anatomy derived from individual practical examination of the human body and investigations which the student can himself repeat as opposed to scientific abstractions." Ever at pains to further the progress of his students he endeared himself to them by his kindly manner and ready sympathy with their work, and his loss will be deeply felt by all who have received his valued training. Up to the actual moment of his death he devoted himself to the teaching of human anatomy in the primary sense of the term. Of that which can be seen with the naked eye by cutting up the *dead* body Mr. Cooke became and continued throughout his life the most distinguished exponent in this country. His classes were attended not by the junior students, but by those who, whether they had failed at examinations or not, had already spent the time usually allotted to anatomy at a medical school, but who had not gained the minimum amount of knowledge required. By personal influence he was able to obtain an application to the study of anatomy on the part of those who had failed to study before and to control by discipline men who had not been amenable to that applied at their own school. Both by word and by writing Mr. Cooke was a most enthusiastic advocate of anatomy as learnt by dissecting, and in certain instances individuals did more and better dissecting at his school than they had ever accomplished before, while he gave the greatest impulse to the teaching and learning of anatomy by the aid of dissections previously prepared. From the experience drawn from the class of students with which he was most familiar, he argued on more than one occasion in our columns and elsewhere against the increasing amount of morphological and embryological anatomy taught. He would concentrate the attention of students upon that irreducible *minimum* of anatomy which they must acquire before qualifying for medical practice. This limitation of the subject can continue to justify itself only by being strongly practical. It must be influenced throughout by the surgical and medical practice of the moment, not by that of the past. The teaching which "caused the dry bones to live" in the sixties or the seventies will not do so now unless revised and brought up to date. That irreducible minimum of anatomy which Mr. Cooke so earnestly taught is not sufficient for the practitioner unless the *living* body is constantly referred to by a surgeon engaged in the active practice of surgery. This side of the question was perhaps not quite clear to Mr. Cooke, who had his ideals and was true to them, but whether we agree with his views or not the fact remains that he was a great anatomical teacher.

Mr. Cooke's contributions to medical literature are well known. We may incidentally mention Tablets of Anatomy, Dissectional and Scientific, the latest edition of which occupied his leisure time during the last years of his life; Tablets of Physiology; Aphorisms of Applied Anatomy; Operative Surgery; Dissection Guides; A Plea for Practical Worth in Anatomy; and the Old and New Schools of Anatomy.

In 1870 Mr. Cooke married Aglaé, daughter of the late Jean François, 21st Comte de Hamel de Manin, Knight of the Royal Order of the Legion of Honour, Officer of the Household of Louis XVIII., and of Helen Marian Rhys, daughter of the late Lieutenant-Colonel John Hughes Rhys, J.P., of Killmaenlwyd Hall, and Pembrey Court, Carmarthenshire, by whom he leaves three sons (of whom one is preparing to follow his father in the medical profession) and two daughters (of whom one is a staff nurse at St. Bartholomew's Hospital). Mr. Cooke was a fervent Christian, an ardent enthusiast, and an incessant worker both in his profession and in his daily life, and had undoubtedly undermined his strength. On the morning of his death he delivered a lecture and was demonstrating in the dissecting-room when the fatal seizure took place, so that in the most literal sense he died in harness.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in January the following candidates were successful in the subjects indicated:—

INTERMEDIATE EXAMINATION IN MEDICINE.

Excluding Physiology.

First Division.—Michael Aldy Collins, Guy's Hospital.

Second Division.—Albert Maurice Amsler, St. Bartholomew's Hospital; Alwyn Hewett Bradley, Mason University College; Albert Henry Bygott, Queen's College, Birmingham; William James Davies and Henry Albert Ehrlich, Guy's Hospital; Daniel Cyril Evans, University College, Cardiff; George Evans, Guy's Hospital; Edward Fow Fisher, London Hospital; Bessie Marion Gifford, Royal Free Hospital and Birkbeck Institute; Arthur Claypon Horner Gray, Guy's Hospital; Percival George Harvey, St. Bartholomew's Hospital; Bernard Watson Jones, Mason University College; William Henry Jones, London Hospital; Charles Burnage Penny, Guy's Hospital; Marie Louise Pethick, London School of Medicine and Royal Free Hospital; Herbert Harland Raw, St. Bartholomew's Hospital; Ernest Frederick Reeve and William Morton Robson, Guy's Hospital; Emily Gertrude Stuart, London School of Medicine and Royal Free Hospital; George Orissa Taylor, London Hospital; David Herbert Trall, Guy's Hospital; Arthur Beaumont Waller, London Hospital; Winefred F. Wigglesworth, London School of Medicine and Royal Free Hospital; and Alfred Ernest Freear Wilkes, Queen's Faculty of Medicine, Birmingham.

Physiology only.

First Division.—Hans Frederick William Boeddicker, Mason University College; Adrian Caddy, St. George's Hospital; David Ellis, London Hospital; Ambrose Hilton John, Robert Archer Lloyd, and Ernest Charles Mackay, St. Bartholomew's Hospital; Annie Mooney, London School of Medicine for Women; Sidney James Ormond, Arthur Pearson, and Alan Carpmael Ransford, Guy's Hospital; and Arthur Stanley Woodwark, St. Bartholomew's Hospital.

Second Division.—James Connor Maxwell Bailey, St. Bartholomew's Hospital; Edward Walter Bain, London Hospital; Herbert Cecil Barlow, Westminster Hospital; Francis Joseph Birks, University College, Sheffield; Norman Carpmael, St. Thomas's Hospital; Francis Gerrard H. Cooke, Cooke's London School of Anatomy; John Stansfield Gayner and David Forsyth, Guy's Hospital; Arthur Charles Sydney Balch Green, St. Bartholomew's Hospital; Oswald Haslam, St. Thomas's Hospital; Ernest Thomas Jensen, William Marriott, and Thomas Arnold Matthews, Guy's Hospital; Allan Chilcott Panckridge Panckridge, Middlesex Hospital; Morgan James Parsons, St. Thomas's Hospita and King's College;

Rees, Guy's Hospital; Charles Haldane Denny Robbs and James John Sheat Sersse, St. Bartholomew's Hospital; Douglas Wilberforce Smith, Edinburgh University and Guy's Hospital; James Henry Stormont, Mason University College; and Frederick George Thompson and William Arthur Trumper, St. Mary's Hospital.

PRELIMINARY SCIENTIFIC EXAMINATION.

Entire Examination

First Division.—David Isaacs, University Tutorial College.

Second Division.—Ralph Annesley Fuller, Merchant Venturers' College, Clifton Laboratory, and private study; and George Francis Jones, University College and private study.

Chemistry and Experimental Physics.

†William Bain, private study and Middlesex Hospital; William Henry Barnett, Cranleigh School and University Tutorial College; †Helen Chambers, Newnham College, Cambridge, and private study; †Arthur James Edmonds, Owens College; †Olive Muriel Elgood, Birkbeck Institution; †Kate Knowles, University College, Nottingham, and University Tutorial College; †Cecil Lionel Lakin, Charing-cross Hospital; †Anthony Richard Neligan, St. Bartholomew's Hospital and private tuition; †William Percy Walker, London Hospital; and †Arthur Denham White, St. Bartholomew's Hospital and private study.

Biology.

†Henry Howarth Bashford, London Hospital; †Alice Marian Benham, University Tutorial College; Leonard Christopher Blackstone, University and University Tutorial Colleges; George Percival Charles Claridge, St Mary's Hospital; †William Brown Clark, King's College; †Herbert D. Clementi Smith, St. Paul's School and private tuition; †Helen Mary Collen, University Tutorial College and private study; †Cecil Colmer, London Hospital; Isaac Reginald Cook, University Tutorial College; Robert Higham Cooper, Charing-cross Hospital; †Albert William Duncan Coventon, Trinity College, Cambridge; †David Morgan Davies, University College, Aberystwith, and Charing-cross Hospital; †Percy Albert Stanley Dyson, Guy's Hospital; Armin Gascoigne V. Elder, St. George's Hospital; Aubrey Geo. Clifton Findlay, University College; †Peter Gifford Foulkes, Middlesex Hospital and Birkbeck Institute; Alexander Harold Gifford, King's College; †Arthur Herbert Gregson, Owens College; Edward Coomber Hobbs, Alwyne Institute; †Alfred Bakewell Howitt, Epsom College; Herbert Vawser Humphry, University College and private tuition; †Catherine Mary Ironside, University Tutorial College; †John Jones, Owens College; †Charles Hugh Lathom, St. Thomas's Hospital and University Tutorial College; George Laurence, University College, Liverpool; Marcus Antonius J. Lavis, Epsom and University Tutorial Colleges and Alwyne Institute; John Trywern Lloyd, University College, Liverpool; †Oswald Edward Lord, St Bartholomew's Hospital; †Lytton Pelham Maitland, the Polytechnic, Regent street; George Ernest Peachell, St. Mary's Hospital; †Percy Alfred Peall, Guy's Hospital; Oscar Phillips Napier Pearn, University College, Aberystwith, and University Tutorial College; †Stephen Hugh Pitcairn and †Geoffrey Price, St Thomas's Hospital and University Tutorial College; †Griffith Henry Rees, Camberwell Grammar School and Guy's Hospital; †Charles Michael Roberts, St. Paul's School and St. Thomas's Hospital; Henry Charles Samuel, University College, Cardiff, and University Tutorial College; †Henry Thomas Samuel, Kingsholme School, Weston-super-Mare; †Frederick William Weeks Smith, St. Thomas's Hospital and University Tutorial College; †Annie Broomhall Thin, University Tutorial College; Ernest Frank Travers, St. Bartholomew's Hospital; †Francis Henry Whitehead, St Thomas's Hospital; †Lorton Alexander Wilson, Owens College; and †Edwin Robert Wheeler, Monkton Combe School and King's College.

† These candidates have now completed the examination.

[N B.—The foregoing list, published for the convenience of candidates, is provisional only and is not final until the reports of the examiners shall have been confirmed by the Senate.]

CONJOINT EXAMINATIONS BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.—The following gentlemen have passed the examination for the diploma in State Medicine and Public Health:—

Honours Division (in order of merit).—Lieutenant-Colonel W. P. Carson, I.M.S., and J. O. Littlewood, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A.

Pass Division.—E. G. Fenton, F.R.C.S., L.R.C.P. Irel.

FOREIGN UNIVERSITY INTELLIGENCE.—*Cracow*: Dr. Michael von Senkowski has been recognised as *privat-docent* of Forensic Chemistry.—*Leipsic*: the medical clinic will shortly celebrate the centenary of its establishment. Marble statues of Professor Wunderlich and Professor E. Wagner will be erected in the gardens of the St. Jacobs Hospital. Dr. Georg Köster has been recognised as *privat-docent* of Internal Medicine. Dr. Hans Held of the Anatomical Institute has been appointed Extraordinary Professor.—*Prague (German University)*: Dr. Ludwig Knapp has been recognised as *privat-docent* of Gynæcology.—*San Francisco (Cooper Medical College)*. Dr. W. Fitch-Cheney has been appointed to the chair of Medicine and Dr. Rixford and Dr. Stillmann have been appointed Professors of Surgery.

ABERYSTWITH INFIRMARY.—The annual meeting of this institution was held on Feb. 4th under the presidency of Mr. J. G. Bonsall. The report showed that the in-patients numbered 191 and that 1648 out-patients were treated. The financial statement was satisfactory.

BRISTOL MEDICAL DRAMATIC CLUB.—The members of the Bristol Medical Dramatic Club celebrated their twenty-second anniversary by giving performances of Pinero's comedy *Dandy Dick* at All Saints' Hall, Clifton, on the evenings of Feb. 7th, 8th, 9th, and 10th. The entertainment was in aid of the Bristol medical charities.

HEALTH OF BATH.—At the meeting of the Bath Sanitary Committee held on Feb. 7th Dr. W. H. Symons, the medical officer of health, reported that the death-rate of Bath for 1898 was 16·3 per 1000. The zymotic death-rate was 1·43 per 1000. The deaths under one year per 1000 births were 136, compared with 161 in England and Wales.

CLIFTON DISPENSARY.—The annual meeting of this institution was held on Feb. 7th under the presidency of Canon Wallace. The report stated that 3681 patients had been treated during 1898, being a decrease of 400 as compared with the preceding year. The income of the dispensary amounted to £753 and there was a favourable balance of £199.

DIPHTHERIA AT ABERDARE.—At the meeting of the Aberdare Urban District Council held on Feb. 10th the medical officer of health (Mr. David Davies) stated that during the preceding two weeks there had been 143 cases of diphtheria, being an increase of 37 on the previous fortnight, and that 9 deaths had occurred from the disease. Mr. Davies recommended that all the schools should be closed for a month.

TWO PLUCKY MEDICAL MEN.—On Feb. 8th a fire broke out at the Aberdeen Lunatic Asylum. All the patients were with some difficulty removed to a place of safety with the exception of one, a woman, who endeavoured to escape by a barred window. She thrust her head and shoulders through the bars and then found that she could neither go forwards nor backwards. The two medical officers seeing her danger procured a ladder and put it to the window. Dr. W. R. Matthews mounted it while Dr. D. R. Moir held it steady as it gave way. Dr. Matthews reached the window and although the bars were very hot succeeded in wrenching them out, so being enabled to pull the woman through with her hair and clothes on fire. Dr. Matthews's hands were burned by the hot iron.

UNIVERSITY OF CAMBRIDGE.—Dr. G. Sims Woodhead, Director of the Laboratories of the Royal Colleges in London, has been elected to the Professorship of Pathology, vacant by the death of Dr. Kanthack. Mr. J. Stanley Gardiner, M.A., Fellow of Caius College, has been elected Balfour Student in Zoology. Grants from the fund have been made to Mr. J. S. Budgett and Mr. L. A. Borradaile in aid of their zoological researches. Mr. P. T. Main, St. John's, has been appointed an Elector to the chair of Chemistry, Professor Liveing an Elector to the chairs of Physics and of Anatomy, Dr. Vines an Elector to the chair of Botany, Dr. Allbutt an Elector to the Downing chair of Medicine, Dr. A. Macalister an Elector to the chairs of Zoology and of Physiology, Dr. L. Humphry an Elector to the chair of Surgery, Dr. Bradbury an Elector to the chair of Pathology, and Professor Foster an Elector to the chair of Mental Philosophy. Mr. H. E. Durham has been appointed a member of the State Medicine Syndicate. Dr. Ruhemann has been appointed an Examiner in Pharmaceutical Chemistry.

CREDITON BOARD OF GUARDIANS AND MIDWIFERY FEES.—At the Crediton County-court on Feb. 9th Mr. C. H. Haycroft, M.R.C.S. Eng., L.S.A., of Bow, sued the Crediton Board of Guardians for a midwifery fee of half a guinea. Evidence showed that Mr. Haycroft who is a district medical officer of the board on Sept. 14th last received an order from the overseer to attend a woman in her confinement. The solicitor who represented the guardians contended that as the husband was not destitute the board was not liable; the overseer or the husband, he added, might be. His Honour Judge Woodfall in giving judgment for Mr. Haycroft stated that it would be putting on a medical officer an intolerable burden if he had to ascertain the circumstances in which the people were living and had to pause before giving his attendance and institute a cross-examination or some other mode of inquiry to see if the people were destitute. His Honour added that he did not think the Poor-law Act meant that kind of medical relief to be administered in any such grinding spirit. The medical officer was bound to obey the

HERTFORDSHIRE COUNTY ASYLUM, Hill End, St. Albans.—Assistant Medical Officer, unmarried. Salary £130 per annum for the first year, rising to £150 per annum after one year's service, with furnished quarters, board, washing, and attendance.

HUDDERSFIELD INFIRMARY.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with board, lodging, and washing.

LEEDS UNION.—Assistant Medical Officer for the Workhouse, Schools, and Infirmary, situate in Beckett-street, Leeds; unmarried. Salary £100 per annum, with board, washing, apartments, and attendance. Subject to statutory deduction. Applications to the Clerk, Poor-law Offices, East Parade, Leeds.

MANCHESTER CHILDREN'S HOSPITAL.—Junior Resident Medical Officer for six months, unmarried. Salary at the rate of £80 a year, with board and lodging. Applications to the Secretary, Dispensary, Gartside-street, Manchester.

MANCHESTER EAR HOSPITAL, 23, Byrom-street.—Clinical Clerkship for a Senior Student for six months. Honorarium 10 guineas.

NORFOLK AND NORWICH HOSPITAL, Norwich.—House Surgeon for two years, unmarried. Salary £80 per annum, with board, lodging, and washing.

PETERBOROUGH INFIRMARY AND DISPENSARY.—Assistant Physician and Assistant Surgeon.

PRESTON ROYAL INFIRMARY.—A Junior and an Assistant Surgeon. Salaries £80 and £50 per annum respectively with board, lodging, washing, &c.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

ROYAL HALIFAX INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with an extra allowance of £9 2s. 6d. per annum; also residence, board, and lodging.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Junior Out-patient Surgical Officer. Salary £50.

SALFORD ROYAL HOSPITAL.—House Surgeon for twelve months. Salary £100 per annum, with board and residence.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Marylebone-road, London, N.W.—Anæsthetist. Honorarium, £20 per annum.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—House Surgeon. Salary £100, with board and residence.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—Assistant House Surgeon. Salary £30 per annum, with board, lodging, and washing.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Assistant House Surgeon, for six months. Board, lodging in the hospital, and washing provided.

UNIVERSITY COLLEGE, Sheffield.—Demonstrator in the Bacteriology Laboratory. Salary £150.

UNIVERSITY OF GLASGOW.—Chair of Pathology. The normal salary of the Chair is fixed by Ordinance at £1100.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—House Physician, for six months. An honorarium at the rate of £50 per annum given, and board and lodging in the hospital provided.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £60 per annum, with board and residence in the hospital.

WINDSOR ROYAL INFIRMARY.—House Surgeon, unmarried. Salary commencing at £100 per annum, with residence, board, and attendance.

WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL, Wolverhampton.—Assistant House Surgeon, for six months. An honorarium at the rate of £50 per annum given at the end of that term. Board, lodging, and washing provided.

Births, Marriages, and Deaths.

BIRTHS.

GUILDING.—On Feb. 8th, at Worcester House, Reading, the wife of Lansdowne Murray Guilding, M.B., of a son.

HALDANE.—On Feb. 13th, at Viewforth, Bridge of Allan, N.B., the wife of William Haldane, M.D., F.R.C.P., of a son.

MACMILLAN.—On Feb. 8th, at Monsall Lodge, Prestwich, Lancashire, the wife of David Macmillan, M.D., of a daughter.

SAYRES.—On Feb. 12th, at Woodford, Essex, the wife of A. W. F. Sayres, M.D., of a son.

MARRIAGES.

SHAW—SCHMOCKER.—On Jan. 25th, at the St. Marylebone Registrar's Office, privately, John Shaw, M.D. Lond., M.R.C.P. Lond., of 32, New Cavendish-street, Cavendish-square, W., to Rosa Schmocker of Ringgenberg, near Interlaken, Switzerland.

WOODS—CHALONER-SMITH.—On Feb. 11th, at St. Bartholomew's Church, Dublin, Hugh Woods, M.D., of Highgate, to Tempe, elder surviving daughter of the late John Chaloner-Smith, C.E., of St. Helen's, Bray, co. Wicklow.

WOODYATT—ROWCROFT.—On Feb. 9th, John F. Woodyatt, M.R.C.S., L.R.C.P., of Halifax, Yorkshire, to Violet Isabel, youngest daughter of Major-General G. C. Rowcroft, I.S.C., of Hampden Mount, Caterham Valley.

DEATHS.

CLARKE.—On Jan. 20th, at Bream Down, Morley, Georgina, the beloved wife of Arthur Clarke, L.R.C.P. Lond., M.R.C.S., aged 42 years.

COOKE.—On Feb. 8th, at his residence, Brunswick-square, suddenly, Thomas Cooke, M.D., F.R.C.S. Eng., aged 57.

DICKINSON.—On Jan. 27th, at Westby House, Boscombe, Bournemouth, J. B. Dickinson, M.D., M.R.C.S., late of Stalybridge, in his 71st year.

RANSFORD.—On Feb. 12th, Gifford Ransford, M.D. Durh., of Sussex-square, aged 56.

.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat (2 P.M.).

TUESDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (22nd).—St. Bartholomew's (1.30 P.M.), University College, (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (23rd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (25th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (20th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. S. West: Some of the Clinical Aspects of Granular Kidney. (Lettsomian Lecture.) Lecture II.—Syllabus: Albuminuria in Granular Kidney. Physiological Albuminuria; postural, dietetic, cyclical, intermittent albuminuria. Albuminuria in the apparently healthy. The different forms of albumen, and the value of the different tests used to detect them. The frequency of albuminuria varies at different ages, and has different significance. Two broad groups: 1. From 25 years onwards.—Albuminuria and Granular Kidney increase in frequency *pari passu* with age. Importance of Albuminuria in relation to life insurance. 2. Up to the age of 25 years.—Frequency of Albuminuria in infancy, childhood, at school-age, and in early adolescence; its significance; in no case, strictly speaking, physiological. Albuminuric retinitis, a late sign. Rare in chronic Parenchymatous Nephritis. White patches the earliest change, but preceded by recognisable changes in vessels. Exists long without impairment of vision, but failure often sudden. Of grave significance, for life rarely preserved long after its occurrence. Amblyopia, Detached Retina. Other eye changes dependent on hæmorrhage. (Various tests for albumin will be demonstrated and cases and specimens shown as far as practicable.)

TUESDAY (21st).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—Discussion on Pseudo tuberculosis. To be opened by Dr. G. S. Woodhead, and continued by Prof. S. Martin, Prof. J. MacFadyean, Dr. Washbourn, Dr. Wethered, Mr. Fullerton, and Mr. Pakes. (Illustrated by microscopic and lantern slides.)

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Mrs. I. W. Wallis: Mental Hygiene as a Basis for Character Formation.

CHELSEA CLINICAL SOCIETY (Holy Trinity Parish Hall, Pavilion-road, S.W.).—8 P.M. Card Specimens: Dr. Vinrace: Ulcerative Perforation of the Stomach. 8.30 P.M. Papers:—Dr. G. Herschell: Atony and Dilatation of the Stomach.—Dr. Penny: Radical Cure of Hydrocele.

WEDNESDAY (22nd).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Informal Exhibition of Cases. 5 P.M. Ordinary Meeting.

HUNTERIAN SOCIETY.—8.30 P.M. Mr. C. J. Symonds: The Value of Individual Symptoms in Perforative Peritonitis, more especially in regard to Operation.

FRIDAY (24th).—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.45 P.M. Special General Meeting.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Clinical Evening. The following cases will be shown:—Dr. Rolleston: Multiple Periarticular Bursæ.—Dr. F. P. Weber: Recommencement of Muscular Atrophy long after Infantile Paralysis.—Dr. Cahill: Unilateral Hypertrophy of the Female Breast resulting from Pressure.—Dr. Caley: A Case of Tabes Dorsalis with Arthropathy and Pulmonary Fibrosis.—Mr. G. B. Hunt: Rheumatoid Arthritis with enlarged Spleen and Glands in an Infant.—Dr. Washbourn and Mr. W. Arbuthnot Lane: A Patient from whom a Cerebral Tumour was Removed seventeen months ago.—Dr. Mouat-Biggs: Extreme Case of Factitious Urticaria.—Dr. R. Crawfurd: Myositis Ossificans Progressiva.—Dr. L. Guthrie: A Case of Congenital Paralysis.—Dr. StClair Thomson: A Man aged 36 years complaining of Dysphagia found to be affected with Unilateral Paralysis of the Eighth and Bulbar Nerves.—Dr. L. Guthrie: Acute Atrophic Paralysis affecting both Upper Extremities.—Mr. E. W. Roughton: Tumour of Maxilla of Doubtful Nature. Patients will be in attendance at 8 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (20th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Dr. T. G. Brodie: The Chemical Pathology of some Infective Diseases. (Erasmus Wilson Lecture.)

TUESDAY (21st).—WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck st., W.).—4 P.M. Dr. T. D. Savill: On the Slighter Forms of Mental Disorder and how to deal with them.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. Horsley: Surgery of the Nervous System (lantern demonstration).

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. E. Ray Lankester: The Morphology of the Mollusca.

WEDNESDAY (22nd).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Dr. T. G. Brodie: The Chemical Pathology of some Infective Diseases. (Erasmus Wilson Lecture.)

EVELINA HOSPITAL (Southwark bridge-road, S.E.).—4.30 P.M. Dr. G. Carpenter: Clinical Demonstration on Medical Cases. (Post-Graduate Course).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Wethered: Difficulties of Diagnosis in Pulmonary Tuberculosis.

THURSDAY (23rd).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. G. V. Poore: The Earth in Relation to the Preservation and Destruction of Contagia. (Milroy Lecture.)

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Galloway: Dermatological Demonstration. (Post-Graduate Class.)

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.—4 P.M. Dr. Barlow: Demonstration of Selected Cases.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Dr. A. Macfadyen: Toxins and Antitoxins.

FRIDAY (24th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Dr. T. G. Brodie: The Chemical Pathology of some Infective Diseases. (Erasmus Wilson Lecture.)

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. O. Lodge: Coherers.

SATURDAY (25th).—ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Right Hon. Lord Rayleigh: The Mechanical Properties of Bodies.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1898, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 6*d.*

To be obtained on application to the Manager, accompanied by remittance.

THE CORNISH MADEIRA.

EARLY this month the town-hall of Falmouth was the scene of a meeting of the East Kerrier Rural District Council, *from the deliberations of which body, as reported in the local press, some instructive lessons may be learned. The quoted passages are from the *Western Mercury*. One of the questions before the council was the drainage of Flushing, concerning which a new scheme has been proposed. Mr. Blamey, medical officer of health of the Falmouth Rural and Penryn Urban Districts of Cornwall, in the course of his duties reported a case of typhoid fever occurring at Flushing and pointed out that the house in which the case occurred was a possible source of danger to the community. Two resolutions from a neighbouring parish council were then read, one of which was *to the effect that if the Sanitary Committee* of the East Kerrier District Council went to Flushing and looked at the place for themselves they would not feel justified in sanctioning the expense to be incurred under the drainage scheme, while the other called attention to the language of condemnation which had been used by a clergyman in the vicinity as being detrimental to the village of Flushing as a health resort. At this stage of the proceedings there arose a Mr. J. Cloak of Flushing who appears to have called the clergyman's language "unmannerly, unmanly, and ungentlemanly," thinking that it "would have the undesirable effect of preventing people from coming to the Cornish Madeira." He was followed by a Mr. Dunstan who "had lived in Flushing for nine years and enjoyed the best of health. If a man had a bit of a cold it was put down to typhoid It was typhoid on the brain. According to what 'these reverends' said Flushing was death for anybody ..... it was the biggest falsehood ever put into print to connect a certain woman suffering from typhoid with the eating of oysters taken from the beds at Flushing" As this last expression was a direct imputation of falsehood upon Mr. Blamey and other medical men in the neighbourhood the speaker was ordered to withdraw his words. This he did after much wrangling

This debate forms a good example of the troubles of the medical officers of health in unenlightened districts. The inhabitants of Flushing object to the publication of the sanitary deficiencies of their village. Instead of trying to set their houses in order they attempt to cajole or browbeat responsible persons into silence that they may enjoy the money of the visitor whose health they are prepared to subject to all the risks rife in a place which is (to use Mr. Blamey's words) "riddled with cesspits." The medical officer of health in such cases has to be very firm. He knows that his action is unpopular and may lose him patients, while his official salary in many, nay, most, cases bears no relation to the responsibilities which he has to bear or the duties which he has to discharge and certainly gives him no pecuniary standpoint from which he can afford not to consider on which side his bread is buttered. Does he get proper credit as a rule for his work which is arduous and unselfish? In the case under consideration Mr. Blamey was well supported by the district council and the partisans of a filth *régime* in Flushing have themselves to thank for the publicity which their cesspits have received, but we have before now known the medical officer of health to be left in the cold by those whom he served.

SUGAR-FREE WINES.

To the Editors of THE LANCET.

SIRS,—Being anxious to obtain the above for a diabetic can you or one of your readers inform me if such wines exist, and if they do where they can be obtained?

I am, Sirs, yours faithfully,

Feb. 15th, 1899. *R. S. P.*

THE EFFECT OF TOBACCO ON DEVELOPMENT.

DR. E. STUVERS, President of the Wyoming Scientific College, has given in the American *Quarterly Journal of Inebriety* some surprising statistics illustrative of the effect of tobacco on the development of the young. From measurements of 187 of the class of 1891, Yale, he found that the non smokers gained in weight during the college course 10·4 per cent. more than the regular smokers and 6·6 per cent. more than the occasional smokers In height the non-users of tobacco increased 24 per cent. more than the regular users and 12 per cent more than the occasional. In increase of chest girth the non users had an advantage of 26·7 per cent. and 22 per cent and an increase of lung capacity of 77·5 per cent. and 49 per cent. respectively. These observations with respect to the dwarfing effects of tobacco are confirmed by observations of the class of 1891, Amherst, made by Dr. Edward Hitchcock. He found that in weight non-smokers increased during their course 24 per cent. more than the smokers; in increase in height they surpassed them 37 per cent., in gain of chest 42 per cent., and in gain of lung capacity 75 per cent. We should be sorry to see these statistics quoted as particularly instructive, for the numbers on which they are founded are too small for trustworthy inferences.

THE SALE OF CATHETERS TO THE PUBLIC.

DR. BARELLA, a Belgian provincial practitioner, has recently been speaking pretty strongly at a [illegible] of the [illegible] *de Médecine* on the subject of criminal [illegible] On looking through the vital [illegible] for the last 20 years it is ev[illegible] diminished in proport[illegible]

The Milroy Lectures

ON

THE EARTH IN RELATION TO THE PRESERVATION AND DESTRUCTION OF CONTAGIA.

Delivered at the Royal College of Physicians of London

BY G. V. POORE, M.D., F.R.C.P. LOND.,
PROFESSOR OF MEDICAL JURISPRUDENCE AND CLINICAL MEDICINE, UNIVERSITY COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.[1]

Delivered on Feb 23rd, 1899.

EARTH.

MR. PRESIDENT AND GENTLEMEN,—That which we commonly speak of as "earth" is largely composed of excreta and the dead remains of animals and vegetables which, as the result of fresh biological processes, are either returned to the bodies of living vegetable organisms or, after becoming mineralised and soluble, are washed downwards by the rain and ultimately find an exit in the sea. It is obvious that not only does "earth" vary in composition with the varying conditions of subsoil, climate, flora and fauna, but that "earth" must undergo *seasonal variations* necessitated by the vigorous upgrowth in the spring or the decay of the fall—the heat and drought of summer or the flood and frost of winter. The interstices between the particles of "earth" are filled at one time with air, at another time with water, and the line of demarcation between earth and air on the one hand and earth and water on the other is often not very definite. Again, the dust which is suspended in the air and which *settles on everything is liable to contain infective* particles, harmless to breathe but dangerous if they fall upon a wound. It is obvious that such particles may be regarded as belonging to the earth or the air. *Some of them* doubtless emanate from the earth, having been raised as dust; but we must admit that there may be organisms which grow in the air, live in the air, and die in the air without ever touching earth or water and which elude all attempts at identification or artificial cultivation. While there are organisms which may live indifferently in air or water others are probably more exclusive in their obligatory conditions. The mutual interaction of earth, air, and water must never be lost sight of. It is the life in the earth, both vegetable and animal, which helps by its influence on vegetation to maintain the quality of the atmosphere. Again, it is the earth which gives the quality to spring and river water. Pure water is a body of definite chemical composition and pure air is a tolerably definite mixture of gases, and it is not difficult to approximately measure the degree of pollution of either. The chemical composition of earth, on the other hand, is complex and constantly changing and it is not possible for the chemist to fix any standard of quality. The practical agriculturist by the aid of touch, smell, and vision will say at once whether any given sample of earth is foul or pure, sour or sweet, rich or poor, fertile or sterile, and we must perforce content ourselves with the terms used by the practical man. The word "earth" in the ensuing lectures will usually be regarded as meaning humus in a healthy condition.

PATHOGENIC SAPROPHYTES.

There are certain pathogenic organisms which are constantly found in the earth and which appear to be ubiquitous. They adhere to *our skins and* clothing, get under the nails, and lodge in the hair. They produce various diseases of wounds and wounded persons and we now recognise that in the absence of *those precautions* which we call "antiseptic" it is never safe to inflict even the smallest wound. The modern surgeon not only renders his hands and instruments aseptic but he operates in *spotless* garments and endeavours to have an operating-room as clean and free from dust as possible. The organisms which produce the various wound infections are saprophytes which flourish external to the body. They are ubiquitous and (probably) necessary and so long as we have a whole skin and uninjured *mucous membrane they do us no harm. As all organic* matter is constantly circulating, passing through death to other forms of life and necessarily undergoing humification as *it does so, it follows that* the agents of these changes, the microbes which are to this end hatched in the soil, vary with the circumstances. Houston[2] gives the estimated number of microbes per gramme found in 21 samples of soil. These vary from 8326 in a virgin sand and 475,282 in a virgin peat to 115,014,492 in the soil from the trench of a sewage farm. Broadly speaking, the microbes bear a proportion to the amount of dung. Warington estimated that a gramme of dung from a cow fed on hay contained 165,000,000. They all, presumably, have their optimum conditions—chemical and physical qualities of the nutritive medium, access of air or other gases, lightness or darkness and temperature—and when the optimum conditions concur growth and multiplication go forward at a pace which we can *hardly* appreciate. The *fact that for the growth of* some the access of air is necessary while others obtain their oxygen from the medium in which they grow and others *again are able to take in oxygen from either source has* formed the basis of a classification which has assisted our *understanding. Saprophytes, including those which produce* wound infection, are presumably of service in bringing about the decomposition of complex organic bodies. Whether we are able to check the growth and multiplication of these facultative parasites outside the body is doubtful and whether or no we should be gainers or losers by so doing is still more doubtful. Bacteriologists have experienced no little difficulty in discovering the exact conditions which are necessary for the growth and development of many of the micro-organisms which have been studied. Some are more exacting than others and those which are best able to accommodate themselves to varying circumstances naturally obtain the mastery when several are attempting to grow simultaneously in the same medium. Some of the larger saprophytes, such, for instance, as the common mushroom, require *no little skill for* their artificial production. Their cultivation requires far more attention to exact details than is necessary with ordinary green-leaved garden plants. We *know that for a few weeks* in the autumn *they may* appear in great numbers in dry pastures where horses have been fed, provided the conditions of the air as to temperature, light, and moisture *be favourable, and we also know that directly* the necessary conditions fail the mushroom harvest is at an end. We also know how strange is the predilection of certain fungi *for the dung of particular animals* and *I would* allude to a list furnished to me by Mr. George Murray, F.R.S., which shows that the optimum conditions for the growth and development *of these short-lived and delicate* organisms must be marvellously subtle and probably quite beyond the ken of the chemist.

I will now proceed to deal seriatim with some of the contagia which are best understood and will begin with

TETANUS.

Among the ubiquitous organisms which are habitually found in earth is the bacillus of tetanus. It is said to be present in almost all rich garden soils and that the presence of horse-dung favours its occurrence. It is strictly anaerobic and has been artificially cultivated by Kitasato in an atmosphere of hydrogen. It forms spores and grows best at a blood heat. Marchesi has found it at a depth of two metres but no lower. The pure cultivation of the bacillus which has a disagreeable aromatic odour is often not very virulent. It is fatal to animals as well as man and among animals the horse appears to be most liable to be attacked. Infection always takes place by inoculation through the wounded skin or mucous membrane—never, it is believed, through the healthy alimentary or respiratory tracts. Cases of "idiopathic" tetanus are reported, but it has fallen to the lot of few of us to see a case and professional opinion seems to lean to the idea that in such cases the inoculating wound has been overlooked. The toxin which the bacillus brews locally in the wound is toxic to the central nervous system and the antitoxin to be effectual must, it is said, be injected subdurally into the central nervous system. The exhaustion of the nervous system seems to increase its vulnerability which is, perhaps, the reason why tetanus has been relatively common in the domain of military surgery. There seems to be no doubt as to the ubiquity of the tetanus germ. Every child who falls on the ground and gets an abrasion of the skin, all tillers of the soil who get accidental wounds in the course of duty, and every horse which "breaks its knees" by falling in the London streets, runs, potentially, a risk of inoculation with tetanus. In the face of the ubiquity of the cause the rarity of the disease is remarkable. I have made inquiry of many practitioners in the Thames Valley where market gardening is the chief industry and where countless tons of London horsedung are spread upon the land and learn from them that tetanus is in their experience the rarest of diseases. Seeing that the bacillus is so strictly anaerobic one is justified in supposing that the tillage of the soil which brings it in contact with air and sunshine must be unfavourable for its growth and virulence. The bacilli must die out under such conditions and the inoculation of the spores alone is said by Vailliard, Rouget, and Vincent to be incapable of setting up tetanus. If the bacillus or the spore be carried in dust, or if they be washed into the water and drunk we have no evidence that any harm results therefrom. In common with some other microbial diseases tetanus is more virulent in the tropics than in temperate climates. Friedberger and Frohner state that it is so common among horses in St. Domingo, especially after the operation of castration, that geldings are worth twice as much as stallions.

---

[1] *Lectures II. and III. will be delivered on Feb. 28th and March 2nd, 1899, respectively.*

[2] Local Government Board Report, 1897-98.

The statement made by Ledantec and H. M. Stanley that the natives of the New Hebrides and Central Africa are in the habit of poisoning their arrows by smearing them with mud (obtained in the New Hebrides from a mangrove swamp) gives emphasis to the importance of a tropical temperature and the absence of tillage as factors which make for increase of virulence of the tetanus bacillus and other organisms found in earth. Pus from the wound of an animal suffering from tetanus is capable of conveying the disease and perhaps it is due to this fact that certain stables and pastures have at times acquired an evil reputation in respect of tetanus. Captain Hayes, F.R.C.V.S., is of opinion that wounds in the hoof as the result of careless shoeing are a great cause of what may look like idiopathic tetanus in horses. In an article by Mr. Sidney Villar in the *Journal of Comparative Pathology and Therapeutics* for December, 1897, an observation by Mr. Joseph Woodger is quoted to the effect that tetanus is particularly common among horses used in dust-carts and Mr. Villar continues: "In my own practice in Middlesex there are two farms where the disease is specially prevalent. One of these at Alfreton is occupied by a farmer who habitually spreads on his fields large quantities of London refuse; at the second farm, five miles away, the bailiff brought two large loads of the sweepings of London roads in 1893 and dressed his home meadows with it. On these meadows his colts and young stock were pastured and for two and a half years tetanus was endemic on his farm; during this period six colts became affected and I believe only one entirely escaped the disease."

This experience of Mr. Villar seems to point to the danger of placing upon grazing land material which is probably mixed with broken glass or crockery. On clay lands such as are common in the north of London manurial matters placed on a pasture would be long in getting incorporated with the soil, and to allow horses to browse amongst the crude impurities of a great city cannot be without danger to the horses. Municipal authorities who wish to find a ready market for street refuse must clearly take care that it is not mixed with dangerous materials of no manurial value likely to wound the feet of animals. In connexion with Marchesi's observation that the tetanus organism has not been found at a greater depth than two metres I would allude to a fact to which I shall return later that this approaches the maximum depth to which the earthworm burrows. It is obvious that if a spore were carried downwards by a worm it would there meet with anaerobic conditions favourable for its preservation. A review of the main facts connected with tetanus cannot but rouse in us some surprise that in face of the ubiquity of the cause the disease in man should be so rare. This is probably in part due to the fact that we wear boots.

ANTHRAX.

Anthrax is a disease which undoubtedly is connected with the soil. The bacillus was discovered by Pollender in 1849, a discovery which is just 50 years old and which marks the dawn of pathological bacteriology. The identification of the bacillus in the laboratory and the diagnosis of the disease in animals from quarter-evil and septicæmia is not without difficulty. These difficulties are now understood but they are sufficient to throw a shade of doubt over some of the earlier observations. It may be well in the first place to give some of the facts collected by Pasteur without comment.

M. Chamberland, the able assistant of M. Pasteur, in his work[3] gives a *résumé* of what one may call the modern history of charbon. In 1842 a Government report showed that in France the disease raged among the flocks of half-bred merino sheep belonging to farmers in La Beauce. It especially attacked lambs and the losses in this district of La Beauce amounted to as much as 20 per cent. (out of a total of some 1,300,000 sheep) "et souvent dans les localités dont le sol est sec et calcaire la mortalité va jusqu'au quart, au tiers et dépasse parfois la moitié du troupeau." In the department of Seine-et-Marne and in the districts of Provins, Fontainebleau, and Meaux are certain farms known as *fermes à charbon*—"les meilleurs cultivateurs ne les louent qu'en tremblant." Also in Le Cantal charbon is known as "mal de montagnes" and certain hills are known as "montagnes maudites" because of their evil reputation in relation to charbon. The animals stricken with charbon show for a few days some excitability and passing dyspnœa and they become distended after feeding. Next the urine becomes bloody and it is a sign of bad omen to see fleeces spotted with blood. The dung also is noticed to be soft and slimy, of a whitish colour stained with blood. They die at last somewhat suddenly and in doing so usually void some blood-stained dung and urine and expel bloody froth from the nostrils. Post mortem decomposition is rapid and the animal swells up and blood is expelled from the nostrils. Hæmorrhages are found in the skin and cellular tissue, as also in the viscera which are engorged with blood.

The discovery of bacilli anthracis in the blood clinches the diagnosis. It was in 1850 that Rayer and Davaine described the bacilli and in 1877 Pasteur communicated to the Academy of Sciences the important fact of sporulation observed in these bacilli by Koch and himself, and further pointed out that the bacillus anthracis was essentially aerobic and was quickly destroyed in the blood of the dead animal after the onset of putrefaction. It is important to take notice of the extent to which the ground is soiled by the dung, discharges, urine, and bloody wool of an animal ill with anthrax.

In August, 1878, M. Pasteur fed sheep on lucerne previously watered with a pure cultivation of bacillus anthracis. He says that "in spite of the immense number of spores taken in with the food many of the sheep escaped death. ......The communication of the disease in this way is still more difficult in the case of guinea-pigs." "Nous n'en avons pas obtenu d'exemple dans d'assez nombreuses expériences. Les spores, dans ce cas, se retrouvent dans les excréments. On les retrouve également intactes dans les excréments des moutons." The mortality is much increased when the infected food is mixed with prickly material such as the leaves of thistles and the chopped beards or husks of barley, and the post-mortem examination of sheep rendered "charbonneuses" by fodder of this kind gave reason to suspect that they were in fact really "inoculated" by definite injury by the prickly food to the back of the throat. Of 19 sheep fed on lucerne polluted with spores three died after four, seven, and nine days; of 11 sheep fed on polluted lucerne and thistles three died after three, four, and six days.

It is recognised by professional "knackers" that they run little risk of contracting "charbon" by manipulating dead animals far advanced in putrefaction and both Pasteur and Koch have shown that putrefaction soon destroys the bacilli in the blood and tissues of an animal and that the bacillus anthracis being aerobic sporulation does not take place inside the putrefying body, but is very liable to occur in the blood which escapes from it whether the blood flow upon the earth or upon a dung-heap.

In August, 1878, Pasteur made a necropsy on the body of a sheep and then buried the carcass in M. Maunoury's garden. 10 months and 14 months afterwards Pasteur found spores of anthrax in the earth of this animal's grave and established the fact by the inoculation of guinea-pigs. The spores were found in the surface soil over the grave, although since the burial the ground had not been moved. Similarly spores were found in the soil over the grave of a cow buried two years previously and at a depth of two metres. These spores were found over the graves of dead animals after all the operations of cultivation and harvest. Earth taken at a distance from these graves did not give charbon.

In announcing these facts to the Academy of Sciences in July, 1880, Pasteur says: "I shall not be surprised if doubts arise in the minds of the Academy as to the correctness of these facts. It will be asked, 'Does the earth, which is so potent as a filter, allow these microscopic spores to rise to the surface?' These doubts seem to be supported by facts already published by M. Joubert and myself. We have announced that water from even superficial springs is sterile...... These, in spite of conditions above which make for pollution, keep perfectly pure, which shows that a certain thickness of earth arrests all solid particles." Pasteur attributes the uprising of spores to the action of earthworms and he claims to have actually recovered spores from the bodies of earthworms living in soil polluted with anthrax.

"May not 'earthworms,'" asks Pasteur, "bring other noxious germs to the surface? They are always filled with a mixture and the spores of charbon are in them mingled with germs of putrefaction and septicæmia." Pasteur, at this time regarded the earthworm as the great cause of the dissemination of anthrax. In a footnote Pasteur calls attention to the fact that in Le Cantal there are pastures which from time immemorial have escaped (*sont épargnés*) and others in which from time to time the cattle were decimated and which are known as "*montagnes dangereuses*" which are abandoned without deriving the least profit from them, "at least during several years," says M. Baillet.[4] "This last circumstance deserves great attention. It proves that the cause, whatever it may be, which produces charbon in a locality disappears with time." In Beauce Pasteur saw certain fields in which the folding of sheep had been interdicted for several years—i.e., since the last death thereupon from charbon. "Now we placed flocks of sheep on five of these fields and the mortality was *nil* except in one flock where it amounted to 1 per cent."

---

[3] Le Charbon, Paris, 1883.

M. Colin of Alfort, a professor at the Veterinary School, not being satisfied with some of Pasteur's experiments, a further report was made on May 17th, 1881, by a commission composed of M. Bouley, M. Davaine, M. Alphonse Guerin, and M. Villemin. Earth from a 12 year grave, a three year grave, and from virgin soil was kept at a temperature of 90° C. for 15 minutes and the fine sediment was injected into guinea-pigs. Of five guinea pigs inoculated with 12-year earth on March 19th four died on March 21st and 22nd from septicæmia and one died on March 23rd from charbon. Of five guinea pigs inoculated with three year earth on March 19th, four died from March 21st to 23rd from septicæmia and one died on March 23rd from charbon. Of five guinea pigs inoculated with virgin soil on March 19th none died. One had a small abscess at the seat of puncture. Of six guinea pigs inoculated with 12 year and three year earth on March 30th five died from septicæmia on April 3rd and one died from charbon (12 year earth) on April 3rd. Of three guinea pigs inoculated with excreta taken from the bodies of living earth worms two died from septicæmia and one from charbon on March 30th. Of the 19 animals killed by the above experiments 15 died from septicæmia and four from charbon.

Since 1879 M. Pasteur had asserted that most soils when inoculated were capable of causing death from septicæmia quite apart from any contamination by the death of anthrax animals. Of three guinea pigs inoculated on March 28th with worm castings taken from above the graves of some of the victims of the commune situated on waste land one died from septicæmia on April 1st and two were unharmed.

Pasteur had clearly demonstrated that the anthrax bacillus is essentially aerobic, that it is soon destroyed by putrefaction and that for sporulation free exposure to air and a temperature above 15° C. and under 45° C. are necessary. These facts seem out of harmony with the view that earthworms bring spores from a deeply buried carcass to the surface.

> The following case is quoted by Pasteur.[5] On August 21st, 179C a mare fell dead from anthrax on a causeway (digue) at Houe (Lure et Loir). The animal was skinned and the carcass was dragged by two horses all along this causeway (along which farm animals passed to and fro) with the result that the ground was soiled by the blood and other débris of the dead animal. A large number of the sheep and cows which used this soiled path died. These animals were skinned and buried with the result that the foci of contamination spread and ultimately 500 or 600 sheep succumbed to anthrax. The *skinning and* transportation of an animal dead from anthrax must necessarily be a most dangerous process.

All are agreed that anthrax is a disease *liable to haunt* localities. Thus, in the report of the Board of Agriculture for 1895 I find the following:—

> An undoubted fact in connexion with anthrax is its tendency to recur on certain farms. An examination of the agricultural returns received shows that during 1895 the disease reappeared on 23 farms or other premises in England and six in Scotland where it had been reported in the previous year. From this cause farms come to be regarded as dangerous and their value is very greatly depreciated. In a report issued by the German Government[6] allusion is made to the farm of Parkisch where anthrax was rife. "Numerous outbreaks of the disease were especially remarked when certain portions of the farm were used as pasture and when fodder from these portions was used in the stalls. The former tenant of the farm is said to have buried on different parts of the farm carcasses of animals which had died of anthrax and also to have put the carcasses into the dung heap to use them as manure."
>
> Again, Dlouie is a large estate in Kroloen, district Losen, and is known as a hot-bed of anthrax. It is stated that carcasses of animals which have died from anthrax have been buried with great carelessness on different parts of the fields especially behind the sheep sheds and in a small wood situated some 100 paces from the farm, which also serves *for pasturage, and even in the dung heaps* which together with the straw from under the diseased animals were used for manure.

It is alleged by Friedberger and Fröhner that the spores may vegetate in the soil and surface water quite independently of the animal body. The disease is said to occur among horses, cattle and buffaloes in Eastern Bengal, Manipur, and Burma without the agency of infection and to be in that part of the world a truly miasmatic disease. As spore formation requires something like a blood heat, it is only what might be expected to find the disease becoming endemic among cattle and horses in tropical countries. Where infected *animals drop dung and other* discharges on the soil it becomes impossible to say whether the infective spore originates in the soil or in the animal. The distinction which separates soil from dung is somewhat subtle. These authors assert that "there exists a well marked connexion between the disease and the amount of moisture in the soil. It appears most frequently in lowlands and plains exposed to inundations and great heat." Copeman also asserts that the disease is prevalent on damp soils containing much humus, as, for instance, upon peat bogs and near the borders of lakes and rivers which have overflowed. On the other hand, we have Pasteur speaking of *montagnes maudites* in connexion with anthrax and asserting that the mortality is great in soils which are *secs et calcaires*.

Many of the outbreaks of anthrax in this country have been in the neighbourhood of Bradford and have been traced to the use of infected wool refuse as manure. A map published by the *Board of Agriculture shows* that the outbreaks of anthrax are most frequent in those counties of Great Britain where dry foreign wools, hairs, hides and skins are manufactured into goods. In 1892 there were 42 outbreaks of anthrax in the West Riding of Yorkshire, as against two in the North Riding and one in the East Riding. Wool when used as a manure must take a long time in becoming disintegrated and humified. In this respect it is very different from dung and if wool be infected with anthrax spores it must be a very dangerous manure for a pasture. The chief sources of danger are said by Dr. Bell of Bradford to be the dry wools of goats, alpacas, and llamas which are imported very dry from hot countries. It is the anthrax spore which is the danger and if, as is the case, a high temperature and free admission of air be necessary for sporulation, an excess of water would be unfavourable for that process. There seems a concurrence of opinion that the bacillus anthracis is killed by putrefaction and soon disappears in the unopened and unskinned body. Schmidt-Mühlheim inoculated guinea pigs with anthrax and as soon as they were dead he skinned them and placed the limbs in an incubator at 39° C. The surface of the flesh was soon covered with a whitish film which was found to consist exclusively of anthrax bacilli, in many of which commencing spore formation was apparent. There can be little doubt that the soil becomes infected by the discharges from the living animal and the skinning and other manipulations of the dead one. The advice which is usually given in this country to bury anthrax carcasses deeply and unopened and unskinned is doubtless sound, although it is doubtful if the depth of the grave adds materially to the anaerobism of the surroundings. It is very doubtful if in an unopened body spore formation be possible after a short period of burial. It is clear that the animal should be buried at the spot where it dies and that the spot should be enclosed and planted with a few saplings of some indigenous tree. The value of "quicklime" is doubtful. Whether it be advisable to delay burial until quicklime can be obtained is still more doubtful.

All Pasteur's experiments in relation to graves appear to me to be vitiated by the fact that they took place in an anthrax district and it is very difficult to say whether the spores were derived from the buried animal or from the dung of infected ones which had been used as manure or from the blood stained wool which, we are told, is of "bad omen" in a flock. It is a noteworthy fact that of the 19 guinea pigs inoculated by the Alfort Commission four only died from anthrax and 15 from septicæmia, and that the earth from the three year old grave and from the 12 year old grave conveyed anthrax in the same proportion—i.e., one in four inoculations. There seems no doubt that spores may be found in earthworms or their castings and there is equally no doubt that if the worms have brought the spores from the depths of the earth such spores must have originally been formed on the surface. It is, of course, quite impossible to say whether a worm swallowed the spore on the surface or below it. It is certain that recently dead bodies have no attractions for worms. Such carrion usually forms the food of maggots hatched from the eggs of diptera deposited before burial and of beetles which live in the earth and are soon attracted to it.

There are some [illegible] observers as to the infectivity of food grown on anthrax ground. On the one hand, Pasteur was unable to do much harm to sheep fed on lucerne sprinkled with spores and, on the other hand, we have a story quoted by Pasteur of an old woman whose goat and cow died from anthrax when fed with clover stolen from over a grave two years after the burial of an anthrax animal. It is, of course, impossible to get away from the *post hoc* fallacy in these cases, especially in a country where animal hygiene was utterly neglected and where anthrax was, or diseases resembling it were, rife. In this country we have had no outbreaks of anthrax at all comparable to those which have proved such a scourge in France and other parts of the continent. The loss of sheep from anthrax in England is very slight and the explanation is probably to be found in the relative vulnerability and immunity of the flocks. Sheep in England are rarely housed but are allowed to breathe at all times the freshest of fresh air. Their pastures are changed before the ground gets foul and when food is short they are either killed at once or fed upon imported food. Such a condition of things would be likely to breed immunity to disease of all kinds; and it is noteworthy that tubercle is much less common among sheep than amongst animals which are housed. When flocks are kept partly for dairy purposes and when sheep are housed and breathe a foul air and lie upon filth mixed with earth it is no wonder that disease, especially such a disease as anthrax, is liable to be rife and to be difficult to eradicate.

---

[4] Mémoires du Ministère de l'Agriculture, 1870.

[5] Annales de l'Agriculture, 1ère Série, tome xxx., p. 332.

[6] Report of the British Board of Agriculture, 1894.

Anthrax in the human subject is a rare disease. Man is never infected through the alimentary tract as appears to be the rule among animals. Dr. Bell of Bradford says that "no such case has been recorded in this country." Cutaneous anthrax (malignant pustule) is caused by direct inoculation. It occurs (1) in those who come into contact with infected animals alive or dead; (2) in those who handle offal, skins, hoofs, horns, hairs, wools or other derivatives from such diseased animals; and (3) in countries where the disease is common among animals women and children who do not come into direct connexion with infective material are not infrequently attacked with the disease through the medium of persons, animals, or insects.

Pulmonary anthrax or wool-sorter's disease was first noticed in the Bradford worsted district after the introduction of alpaca and mohair as textile materials in 1837. "This form of anthrax may attack any person exposed to the inhalation of anthrax spores in *dust* arising from the products of diseased animals." The fact appears to be undoubted that anthrax may be a dust disease and that the spores when perfectly dry may be inhaled into the lungs. And yet I have hitherto found no records of pulmonary anthrax from the inhalation of dust from highly manured ground which must, one would suppose, especially in the West Riding of Yorkshire, often contain anthrax spores. The lungs of the agricultural labourer and the market gardener appear to be immune to the infectivity of anthrax spores. It seems to be of very great importance to bear in mind: (1) that anthrax spores persist even in the finely pulverised soil of worm castings, which must be very easily dried and converted into dust; (2) that anthrax may undoubtedly infect man by the inhalation of dust; and (3) that pulmonary anthrax among agriculturists has not been recorded. In India it is believed by some that dust is a common cause of enteric fever among Europeans, a statement which is insusceptible of proof or of disproof. Does pulmonary anthrax occur among the rural population of the tropical countries where the disease is endemic amongst cattle? In this connexion we must bear in mind that anthrax bacilli may change their virulence without undergoing any morphological changes and in this form when inoculated may confer immunity on susceptible animals without apparently producing other effects. The virulence is diminished by cultivation at high (from 108° to 120° F.) or low (from 66° to 75°) temperatures, by cultivation under pressure of three or four atmospheres, by exposure to sunlight, or by admixture with other bacteria. The modified organisms thus produced are not pathogenetic but confer immunity on susceptible animals for nine or 12 months. Morphologically they are indistinguishable from the most active and virulent forms of the organism and they will generally regain their virulence when favourable conditions are restored although the degree of virulence varies in different species of animals. The persistence of the anthrax spore in the earth does not admit of a doubt but there is no evidence that man is ever infected directly from the earth. How far anthrax in animals is due to inoculation rather than to feeding requires further and very careful investigation.

DIARRHŒA.

Diarrhœa is a disease which in its epidemic form has been supposed to be engendered in the earth.

The third quarter of the year 1898[7] was characterised by a very large infantile mortality, mainly attributable to diarrhœa. The rainfall for the quarter was unprecedentedly small, the temperature was above the average, and the harvest was one of the best on record.

Of the 141,540 deaths registered 52,837 were those of infants under one year of age. The mortality of infants, measured by the proportion of deaths under one year of age to registered births, was 225 per 1000 which is the highest proportion in any quarter for which the figures are available and is 55 per 1000 above the average in the 10 preceding third quarters. In the 33 great towns as a whole infant mortality was equal to 275 per 1000 births, being higher than the proportion in England and Wales by 50 per 1000.

Excluding the towns infant mortality in the remainder of England and Wales was in the proportion of 184 to 1000 births. *Diarrhœa* caused 22,524 deaths, equal to an annual rate of 2·85 per 1000, or 1·21 above the average rate of mortality in the third quarters of the previous ten years.

The death-rate from this disease ranged from 0·7 in Rutlandshire, 0·58 in Hertfordshire, 0·66 in Shropshire, and 0·68 in Dorsetshire, to 3·63 in Leicestershire, 3 70 in Staffordshire, 3·94 in Lancashire, 4·23 in the East Riding of Yorkshire, and 4·40 in Warwickshire. Among the 33 great towns the diarrhœa rate averaged 3·85 per 1000, the highest rates being 5·85 in Hull, 5·94 in Sunderland, 6·30 in Sheffield, 6·38 in Wolverhampton, 6·41 in Preston, and 6·47 in Salford. In the 67 other large towns the rate averaged 3·27 per 1000. In the rest of England and Wales the diarrhœa death-rate was equal to 2·07 per 1000.

It will be observed that the mortality from diarrhœa was mainly urban. Among counties it is the rural counties which have least and the industrial counties which have most diarrhœa and if we turn to the mortality returns for those counties where diarrhœa was especially rife we shall find the mortality greatest in the urban districts. It is a point not without interest to note that the diarrhœa death-rate and the fever death-rate in this quarter bore no relation to each other and that, while the diarrhœal death-rate was 1·21 above the fever death-rate was 0·03 below the average for the corresponding quarter of the last 10 years. In the following table some figures are collected which show this very strikingly.

Table showing the Death-rates per 1000 from Fever and Diarrhœa during the Third Quarter of 1898.

—	Fever.	Diarrhœa.
England and Wales	0·16	2·85
London	0·11	3·19
Wolverhampton	0·18	6·38
Leicester	0·13	5·34
Manchester	0·09	5·33
Preston	0·28	6·41

Diarrhœa is a disease of hot weather. Ballard thought that when the four-feet temperature of the earth reaches 56° F. diarrhœa becomes common. Tomkins of Leicester (Leicester is a "diarrhœa town") shows that the disease becomes common when the one-foot thermometer stands at 60°. Snow of Buffalo, U.S.A., showed that in 1886-88 diarrhœa mortality was highest when the minimum atmospheric temperature attained its highest average range. The London statistics for 1887 and 1888 collected by Dawson Williams show a similar relationship between diarrhœa and a high average minimum range of temperature. Copeman considers it highly probable that the disease is due to "microphytic processes" going on in the upper layers of the soil. This would afford an explanation of the fact that summer diarrhœa is especially a disease of cities having a polluted soil. Ballard's conclusions (as given by Copeman) were: "That the essential cause of diarrhœa resides ordinarily in the superficial layers of the earth where it is intimately associated with the life processes of some micro-organism not yet detected, captured, or isolated. That the vital manifestations of such organism are dependent, among other things, perhaps principally upon conditions of season and on the presence of dead organic matter which is its pabulum. That on occasion such micro-organism, capable of getting abroad from its primary habitat, the earth, and having become air-borne, obtains opportunity for fastening on non-living organic material and of using such organic material both as nidus and pabulum in undergoing various phases of its life-history. That in food, inside of as well as outside of the human body such micro-organism finds, especially at certain seasons, nidus and pabulum convenient for its development, multiplication, or evolution. That from food, as also from the contained organic matter of particular soils, such micro-organisms can manufacture by the chemical changes wrought therein through certain of their life-processes a substance which is a virulent chemical poison (probably ptomaine). That this chemical substance is in the human body the material cause of epidemic diarrhœa."

---

[7] Quarterly Return of the Registrar-General.

It is most important to remember that these speculative notions of Ballard's are not facts.

The bacillus enteritidis sporogenes is believed by Klein to be the cause of infantile diarrhœa.[8] It is an anaerobic bacillus which forms spores and may be easily cultivated in milk. It is fatal to rodents when injected hypodermically and produces a foul smelling bloody œdema of the cellular tissue and adjacent muscle tissue. The spores were found in four out of 10 cases of infantile diarrhœa examined and in six out of eight cases of cholera nostras. It was found in eight out of 10 samples of milk purchased in London milkshops between April and the end of June (when diarrhœa was not epidemic?) including samples of so-called "pure sterilised milk." It has been found in large quantities in sewage and in sewage effluents. It is found in horsedung and in all matters polluted with it. It has not been found in pig dung or cowdung or in the dung of a healthy human being.

In face of the wide distribution of the microbe it is evident that the vulnerability of the individual must be an important factor in determining an attack of diarrhœa. If we are to consider diarrhœa as a soil disease it is evident that it exists only in the upper layers. It is more common among city streets than in agricultural districts. According to Klein the probable cause is largely to be found in horse dung which is pulverised and blown about generally. Temperature, as we all know, is most potent as a cause of infantile diarrhœa in cities. That it is a "soil" disease in any true sense is certainly not proven.

DYSENTERY.

Andrew Davidson[9] says:—"In keeping with the predilection of endemic dysentery for marshy localities accounts of its endemo-epidemic extensions in temperate climates generally point to the temporary establishment of paludal conditions." Thus in 1873 an outbreak arose from the cleaning out of the lateral canal of the Loire and the desiccation of the mud. A similar result followed at Leymen (Haut Rhin) from the clearing out in August, 1850, of a vast slimy reservoir situated in the middle of the village. In tropical countries dysentery appears to be more independent of soil than in temperate climates, but an imperfectly-drained or marshy soil is everywhere favourable to its prevalence. The geological nature and the mineralogical constituents of the soil are secondary in importance to its physical conditions—its dryness, humidity, and aeration. These again are of less moment than its state of organic purity. That a soil charged with dysenteric or perhaps even with fæcal (simple fæcal) evacuations is capable of giving rise to the disease is amply proved. The epidemics which occurred in the Cumberland and Westmorland Asylum in 1864-65 and in 1868 were shown by Dr. Clouston to be due to the effluvia from a stiff clay field over which the sewage of the asylum was allowed to flow. The soil was quite unfit for irrigation purposes. Among the causes of the frightful dysentery mortality which made Secunderabad a byword none was more effective than the saturation of the soil of the site itself with organic impurities, the extreme pollution of the vicinity with fæcal matters, and the bad privy accommodation. The dysentery of war and famine shows little respect for climate or season; under the given conditions it appears in countries most free from the endemic disease and at all seasons of the year. The dysentery of war and famine is extremely fatal and it has a greater tendency than any other to become complicated with typhus, typhoid, and malarious fevers. In the Irish workhouses during the 10 years ending June, 1851, no fewer than 50,019 persons perished from dysentery and 20,507 from diarrhœa. The dysentery of war and famine frequently assumes a contagious character. The bacteriology is rather uncertain owing to the numbers and variety of the micro-organisms which are found.

Davidson concludes: 1. The healthy intestine is capable of much resistance to the infective agents of dysentery. 2. The healthy human being carries with him organisms capable under certain conditions of giving rise to inflammation of the intestinal tract, and besides organisms of suppuration, putrefaction, and sepsis are everywhere present which have the power of determining dysenteric inflammation of the bowels when its nutrition is impaired. 3. A simple catarrhal condition of the bowel is sufficient in itself to produce true dysentery. 4. When we observe a body of men seized with an infectious form of dysentery immediately after being subjected to hardship and depressing meteorological influences while another body in the vicinity having the same food- and water-supply but not subjected to the like fatigue and hardships escape, we are led to infer that the common exciters of inflammation rather than any specific agent must have given rise to the disease.

CHOLERA.

Ernest Hart says: "Within certain areas in India cholera is endemic, especially in the country of the lower Ganges. There the air, the water, and the soil are never cold, the ground is often damp, and when it is dry the tanks are foul, so that there is always a fit breeding place for the contagion, &c." Koch's vibrio (Kanthack) grows in dilute peptone at from 30° to 35° C. It is commonly said to be destroyed by drying. It is a facultative anaerobe and highly saprophytic. Cultures retain their vitality on silk threads for 86 days and dried on glass for 120 days. "From flies fed on choleraic material the vibrios could be separated after 14 days." The inoculation test practised on the lower animals is inconclusive. According to Pettenkofer (quoted by Copeman) cholera occurs when the ground-water after having attained a higher level than usual commences again to fall.

MALTA FEVER.

Malta fever[10] is caused by the micrococcus melitensis discovered by Bruce in 1887. It is common to the shores of the Mediterranean and Red Seas. "It was early apparent that its presence in Malta and Gibraltar was connected with fæcal and organic matter from human sources. Sewers and sewage works where those have been undertaken, as in Valetta and Naples, appear to have little influence in diminishing the attacks. Indeed, the channels are so frequently pervious and allow *the fæcal matter to soak into the pores of the soil that they virtually* become elongated cesspools and increase rather than diminish the dissemination of the poison. Tomaselli notices the same fact in relation to the prevalence of the fever and the introduction of sewers into Catania. In his opinion the immense quantity of sewage and sewer air which is developed in these sewers and finds its way out of them is to be placed in the first rank of its causation and is an argument in favour of the aerial dissemination of the morbific agent. The micro-organism grows best in nutrient material the alkalinity of which is slightly less than human blood and at a temperature of from 37° C. to 39° C. It fulfils Koch's postulates at all points. It lives for a long time in the dry state."

PLAGUE.

Plague has been regarded as a soil disease, but recent evidence must materially modify this opinion.

The alleged facts which support this view are, according to J. F. Payne in his article on Plague in Allbutt's System of Medicine: (1) its limited geographical distribution; (2) because ground animals such as rats perish in large numbers—"they have buboes and their organs contain immense numbers of the plague bacilli; it cannot therefore be doubted that the virus exists underground before it affects human beings"; (3) its recurrence at the same spot while places near and in direct communication escape; (4) the escape of water populations such as Canton and in London in 1665; (5) the fact that the ground floor is affected more than the first floor—"Plague does not go upstairs" (?); and (6) "the beneficial effect of local sanitary measures."

It would appear from the above reasons that the endemic prevalence of plague is comparable to that of cholera or typhoid fever and is governed by somewhat similar laws, though in other respects it differs very much from those diseases. In the double infection of the soil and the organism it resembles anthrax. Along with the infection of the soil there appears to be a passage of the virus in some form into the air, so that it has always been believed that the disease may be acquired by inhalation like typhus fever. Scientific explanation of this method of receiving the virus is still wanting. Epidemics have often been preceded by drought; epizootics, famine, and abundance of flies have been noticed. Epidemics are usually checked by cold and heat. It is pre-eminently a filth disease invading by preference the crowded, ill-ventilated hovels of the miserable. "A soil contaminated with fæcal discharges and decaying animal matter of all kinds appears to be an essential condition for the vitality of the virus." Widely different opinions have been held as to its "contagiousness." "The infection is doubtless generally conveyed by persons either infected with the disease or in the state of incubation. Such persons convert the house they occupy into a focus of infection till possibly the virus passes into the soil and a severe *epidemic may result.*" *The rate of extension is* variable but generally slow; plague has taken weeks or months to pass from one side of a city to another; it creeps along from point to point so as to be compared by some to a drop of oil on paper. Such gradual extension suggests the slow progress of a virus in the soil itself, and probably that *is in some* places the explanation, but obviously only transmission through short distances can be thus accounted for.

It is encouraging to observe how the habit of calmly observing and recording the phenomena of different epidemics together with carefully devised experiment has thrown light upon many of the obscure points connected with plague. We now know that plague is protean in its forms and that all forms *are not conveyed from individual to* individual with equal readiness. The unfortunate accident which occurred last year in Vienna ought to have, and doubtless has had, the effect of dispelling many of the superstitions in regard to plague. It has clearly demonstrated to the people at large (1) *that the poison is something* tangible which may be conveyed from one part of the world to *another* in a test-tube; (2) that the poison may infect the lower animals; (3) that the lower animals may infect man; (4) that the pulmonary form of the disease is terribly infectious and communicable through the air; and (5) that measures of disinfection and isolation are capable of cutting short an epidemic. Experiments carried out in districts where a disease is epidemic or endemic necessarily acquire a measure of *uncertainty* from that fact alone. The occurrence at Vienna, much as one may deplore it, was an object-lesson of the greatest value and converted what many regarded as mere theories into facts which all can read and understand. In the recent epidemics in the East the theory that plague grows "in the soil" has received no support whatever and that it spreads in the soil like a drop of oil permeating paper appears to be unlikely. In India two facts have come to the front—viz., the danger in [illegible] of [illegible] rats and

[9] Allbutt's System of Medicine, vol. ii., p. 408.

[10] Allbutt's System of

(*b*) abrasions on the skin. The rat lives in burrows in the soil and swarms in our sewers. He feeds largely at night and comes out of his hole in search of food and prey. It has long been recognised that the rat is susceptible of plague. In Bombay, according to Simpson, as many as 100 affected rats were counted in one small grain depôt in one day. Hindoo writings 800 years old warn the inhabitants to leave a district when they observe a mortality among rats. The infection of rats usually follows infection of a distant locality by men. Nowhere has this been more decidedly proved than during the late epidemic in India, where the infection of the rats has unfortunately followed the introduction of the virus by man, from a primary seat of infection situated at considerable distances from the secondary area of infection. Rats may convey infection from infected burrows on their feet or fur; they also become infected by eating each other. When dying they usually leave their holes and run about the rooms of a house and then die. Carelessness in dealing with or handling them, especially in the filthy surroundings and associated with the dirty habits of the inhabitants of these houses, along with the possible convection by vermin, must all necessarily be in favour of the infection being carried to man. The amount of such infection spread by rats cannot be gauged. The infection of the rat is no proof whatever of infection of the soil except by filth deposited on the surface. Lowson in his report to the Bombay Government in 1897 says: "That the disease is primarily a soil disease is certainly borne out neither by observation nor experiment. Takaki and I carried out bacteriological experiments in Hong-Kong by which we were able to prove that even in houses in which the earthen floors had been severely infected no cases of plague infection could be obtained and later experiments on the artificial infection of earth with a culture of the plague bacillus have shown that the mixture of earth and bacilli loses its infecting power, sometimes in a couple of days." Indeed, there has been no proof forthcoming so far that the plague bacillus has ever been found below the surface of the earth.

In Hong-Kong the soldiers who were attacked by plague were in the cleansing squads, and were well booted, but worked with trousers open at the bottom. In India the military parties who assisted in this work were ordered to wear putties to prevent plague-infected dust and animals from coming in contact with their legs, with the result that none of those engaged in this work became infected, and that, too, amongst probably eight or 10 times more soldiers than were doing the work in Hong Kong. To sum up, it may be said that the following are the most important items in the spread of plague: (1) filthy habits of the people, such as spitting over the floor and others mentioned above; (2) filthy houses; (3) overcrowding and consequent rapid increase of contagious disease when once imported; (4) presence of rats, insects, and other vermin; (5) the naked condition of the people going about, such people presenting almost unlimited opportunities for the entrance into their tissues of plague poison by inoculation and through abrasions; (6) pollution of soil and houses with the excretions of man and animals; and (7) filthy clothing and absence of bodily hygiene.

DIPHTHERIA.

Arthur Newsholme in his work on Epidemic Diphtheria (1898) while admitting that personal infection is the chief means by which diphtheria is spread, contends that:—

> The specific micro-organism of this disease has a double cycle of existence, as have the specific micro-organisms of enteric fever, erysipelas, scarlet fever, rheumatic fever, &c. One phase is passed in the soil, another in the human organism. *One is saprophytic, the other parasitic.*[11] It is not strange, therefore, that the epidemic prevalence of all the above diseases is favoured by deficient rainfall if this is sufficiently long continued. This deficient rainfall implies a low subsoil water and a subsoil above the level of this water which is relatively dry and warm, probably *the optimum conditions* of the saprophytic life of the above pathogenic micro-organisms. The causes of the transition of the diphtheria bacillus from the saprophytic to the parasitic phase of life may be surmised both as regards (*a*) season and (*b*) years of special epidemic prevalence. Diphtheria is most prevalent in the autumn and early winter months, when the optimum temperature and the optimum degree of humidity of the soil are rapidly disappearing or have departed. It is also most prevalent after the wet weather occurring in or immediately following exceptionally dry years. Both these conditions tend to raise the ground water and to drive out any pathogenic micro-organisms from the soil.

Newsholme is of opinion that in order to account for the epidemic and even pandemic waves of diphtheria "the diphtheria bacillus under certain conditions *becomes* more actively virulent and infective—more remote from its saprophytic phase of life, and that thus persons who can resist the ingress of the feebler fall victims to the more powerful micro-organism." The latter is probably the correct hypothesis and the evidence already given clearly points to the conclusion that of the external cultural conditions leading to increased virulence of the diphtheria bacillus and greater readiness for assuming a parasitic life exceptional deficiency of rainfall and consequent exceptional deficiency of moisture in and exceptional warmth of the subsoil form an essential part.

The above is a very ingenious hypothesis, but it is essential to point out that the diphtheria bacillus *has not* been recovered from the soil and that the bacilli of rheumatic fever and scarlet fever have not yet been identified. Before Newsholme's hypothesis can be accepted a great deal more evidence will be necessary.

Newsholme's figures and tables show clearly that the amount of diphtheria is very great in the American cities. He records *death-rates* (per 100,000) for diphtheria of 109 in New York (average of 28 years, 1868-95), 77 in Chicago (36 years, 1859-94), 100 in Boston (35 years, 1861-95), 114 in Brooklyn (1875-95), and 129 in Pittsburg (1877-94). The highest death-rate from diphtheria ever recorded in London was 76 (per 100,000) in 1893. The average death-rate per 100,000 was in Salford 32 (1860-95), Manchester 18 (1871-96), Liverpool 14 (1860-95), and Sheffield 15 (1859-96). The figures were still lower in others of our great industrial towns. In Holland we find death-rates per 100,000 *from* diphtheria alone of seven in Rotterdam, 12 in The Hague, and 31 in Amsterdam (all three for 1879-95). Berlin gives 101 (1869-96), St. Petersburg 65 (1879-95), and Moscow 64 (1878-96). The death-rate in Japan appears to be low.

Newsholme's figures generally seem to show that diphtheria is now a disease more of the towns than of the rural districts. It is not very easy to understand how in a city where pavements and other impermeable coverings to the soil are general the bacillus is driven by the rising subsoil water into the air. Of course, it may be driven out of the sewers and sewer ventilators, in which case it becomes a sewer disease rather than a soil disease. Why is it not an air disease? Nobody who has ever smelt the air of Bond-street in a hot July or who has watched the impurities descending from the upper air when they are driven downwards by the first showers after a drought would refuse to allow to the air of a city any amount of potential infectivity. Most of the facts collected by Newsholme are explained as readily, *if not more readily*, on the theory that diphtheria is an air disease as upon the theory that it is a soil disease. If we remember that a theory is not a fact these speculations will do no harm. Unfortunately this is not always remembered. Diphtheria (Copeman) has been supposed to show a preference for houses on damp clayey soils (Greenhow, Airy) and dampness of habitation (Thursfield). "Although," says Copeman, "dampness of site is undoubtedly a factor in the production of outbreaks of diphtheria, particularly if such dampness be due to persistent leakage from imperfect sewers or cesspools," it does not appear to bear any relation to the rise and fall of the subsoil water.

That diphtheria is a soil disease is certainly not proven.

MALARIA.

A few years ago I should have spoken of "malaria" as undoubtedly caused by something in the soil itself and I should have indulged in the stock phrases about miasmata, mephitic vapours, and the like. The discovery of hæmatozoa in the blood of sufferers from malaria has altered our point of view. The most widely spread poison in the world has become something which is visible and tangible and inoculable. No discovery which has ever been made in the domain of medicine is likely to have such far-reaching effects. Further it seems certain that the infection of human beings may take place viâ the mosquito and we are now concerned to find out whether this is or is not the only medium through which the blood of man receives the *parasite*. Some who are well qualified to speak would answer in one way and some in another. This is not the place for weighing arguments *pro* and *con* nor can I claim any special knowledge which qualifies me to sit in judgment. Let us assume that it may possibly be shown hereafter that what we have hitherto regarded as "malaria" is a parasitic disease wholly and solely inoculated in us by insects of the mosquito class and that in respect of its mediate infection by animals malaria will fall into line with rabies. We cannot issue a muzzling order to be enforced against mosquitoes nor can we lure stray mosquitoes to their death in some tropical Battersea. We shall have to go more to the root of the matter and while on the one hand we may be able to show Europeans the importance of protecting themselves against the attacks of insects we must still continue to make use of our accumulated knowledge as to the conditions of soil which indirectly cause remittent fevers to be endemic. Old and well-established facts will now be re-examined by intellects strengthened and widened by the discoveries of Laveran and Ross, and our knowledge is sure to be extended and increased. Although the conditions of soil which give rise to malaria are too well known to need any lengthy discussion here it may be well to give some of the latest utterances on the subject.

---

[11] It is not contended that there is a regular alternation of saprophytic and parasitic generations; but that such alternations do occur.

Sir Joseph Fayrer writing on the "Climate and Some of the Fevers in India" in Allbutt's System of Medicine[12] says of malaria: "It often appears with great virulence after excavation or turning up of soil and in land that has recently been denuded of jungle." . ... "On the other hand, draining and cropping seem after a time to diminish or destroy the poison. Maclean calls attention to the fact that when excavations were made in the island of Hong Kong which consists entirely of weathered and decaying granite and is liable to be permeated with a peculiar fungus, violent and fatal remittent fever appeared."

Osler says: "An interesting feature in connexion with the disease is the gradual disappearance from certain regions under the influence of drainage and cultivation. In England, even in the fen country it is now almost unknown. In New England, too, it has gradually disappeared. In parts of Canada bordering Lake Ontario which were formerly hotbeds of the disease cases only exceptionally occur." It is well called a soil disease. "Excavations of all sorts, extensive cuttings for railways, and the breaking up on a large scale of virgin soil have in many instances been followed by outbreaks of malaria.[13] "The greater prevalence of fever in the Royal Engineers in comparison with other troops is probably to be accounted for by their more frequent employment in the excavation of the soil. Manson,[14] speaking of Ross's work in connexion with the mosquito, says that although he believes that malaria may be acquired by the bite of the mosquito, he does not believe that this is the only way. Rees of the Seamen's Hospital[15] gives details of an outbreak of intermittent fever (confirmed by examination of the blood by himself and Manson) which affected 22 of the crew of a ship nine days out from Colombo and 14 *from Calcutta on her homeward voyage. Air-borne infection or* water-borne infection cannot be lightly dismissed.

BLACKWATER FEVER.

Crosse, writing on blackwater fever,[16] says: "Some will ask, Why has blackwater fever become so common recently? The first case on record in the Niger Territory was, so far as I know, my own 10 years ago. The first case on the Niger Delta is said by some old coasters to have occurred in 1882. It seems to me that since we have begun to turn up virgin soil for coffee and other plantations the disease has become common. .. It is significant that our first three gardeners died of blackwater fever and that for some considerable time cases only occurred near the plantations, and as plantations became common so the disease spread to the other stations in the territories. Castellote notes a case in which a white man personally superintended the digging of a grave and stood about in the sun for two or three hours; next day he had severe fever which developed into blackwater fever.' According to Battersby "many virulent attacks after the turning up of virgin soil have been recorded. Almost equally remarkable, according to this observer, is the diminution of the disease which has been brought about in certain localities by drainage and cultivation of the soil."

It is generally conceded that the turning up of virgin soil is one of the most fruitful causes of malignant malarial fevers and numberless examples of this are given in text-books on the subject. Surgeon Bowden, R.N., D.S.O., informs me that the turning up of fresh soil is often followed by *an influx of mosquitoes.* On the other hand, the cultivation of the soil seems ultimately to lead to the decrease and disappearance of malaria. The broad facts of nature must convince us that this must be so for if man in his attempts to grow food merely increased the deadliness of his surroundings the human race would soon become extinct.

There is a group of diseases which (like malaria) seem to be dependent upon the bites or stings of insects and which, although they affect animals rather than man, throw much light upon the pathology of infection and teach us that so-called "climatic diseases" may be due to something very gross and palpable.

NGANA OR TSETSE FLY DISEASE.

Kanthack, Durham, and Blandford,[17] show that this disease is due to a hæmatozoon (trypanosoma) in the blood inoculated by a fly. Cats, dogs, mice, rabbits, rats, hedgehogs, donkeys, horses and their hybrids seem susceptible. The disease seems to be communicable only by some form of inoculation and is not probably conveyed by feeding on infective material in the absence of superficial lesions. Material taken from the dead body 24 hours after death is not infective. The nearest lymphatic glands to the inoculated spot are the first to suffer. The hæmatozoon gets through the lymphatics to the blood. In the late stages of the disease the animals (especially dogs) may become infected by pyococci, i.e., a spontaneous infection to which the animal is rendered prone by its marasmus. The blood may contain 3,000,000 hæmatozoa per millimetre or may prove infective though none be visible. The trypanosoma sanguinis which is found in a certain proportion of rats has no apparent relation to tsetse fly disease. A similar parasite is said to cause "surra" in India and an allied disease among horses in Algeria. Surra is probably conveyed by flies. Lingard thinks the fodder soiled with rat-dung may give the disease, but that is doubtful. The tsetse fly is a dipterous insect *somewhat resembling the* common house fly. It has a long thin proboscis, chestnut thorax marked longitudinally by four black lines, and a yellowish white abdomen of five rings. It inhabits principally the low lying and swampy valleys of the Zambesi and Chobe.

"LOUPING ILL."

This disease, which is common in the North of England and Scotland and which has been noticed as fatal to sheep frequenting certain pastures, has now been shown by Williams, Meek, and Greig Smith[18] to be caused presumably by a special kind of sheep "tick" found on these pastures, which tick is supposed to be hatched in the upper layer of the soil and to inoculate the sheep with micro-organisms which cause the disease—a disease which is characterised by staggering and lameness due to congestion of the brain and spinal cord which have been found post mortem.

TEXAS FEVER OF CATTLE.

This appears to be caused by a hæmatozoon with which the animal is inoculated by a tick (ixodes or boophilus bovis) which is parasitic. The Australian tick fever and the ixodic anæmia of Jamaica appear also to be produced by allied if not identical parasitic animals. Principal Williams, F.R.C.V.S. of the New Veterinary College, Edinburgh, in *writing on ixodic anæmia or Texas fever*[19] (which he studied in Jamaica) which is due to the infection of cattle with a blood parasite by the agency of a tick (ixodes bovis) insists that every attempt should be made to get rid of the ticks which breed especially in the vegetable rubbish left upon the pastures. "Every effort should be made," he says, "to conserve and increase tick destroyers such as the black tick birds. . I have had much amusement in watching these birds, as there seems to be an understanding between them and the cattle whereby they are assisted and encouraged to destroy the ticks." Domestic fowls should be encouraged and starlings and song thrushes might be imported. To a stranger visiting the island (Jamaica) the scarcity of birds is a striking feature. I have been told that it is due to the mongoose, which has not only diminished the number of wild birds and domestic fowls, but other tick-destroying creatures such as the ground lizard. Now this destruction of the natural tick destroyers should, as far as possible, be prevented, firstly by legal protection, secondly by encouraging the slaughter of the mongoose." (For further remarks see *Veterinary Journal*, 1896.)

SOUTH AFRICAN HORSE DISEASE.

South African horse disease has no apparent connexion with insects or surface wounds, but appears to depend not upon conditions of the surface soil, but on temporary conditions of the vegetation which *forms the pastures.*

South African horse disease (œdema mycosis) is described by Captain Hayes, F.R.C.V.S., in his translation of Friedberger and Frohner's Veterinary Pathology, and is supposed by Edington to be caused by a mould (penicillium) which grows in the vessels causing thrombosis and exudation of serum with fatal results. It appears to occur chiefly *among animals which are allowed to graze while the dew is on the grass* and the growth of the microbe is supposed to be connected with the dampness of the grass. The disease once contracted is almost always fatal, but the prophylactic appears to be dry fodder and the folding of horses until the sun has dissipated the moisture of the dews.

The history of those diseases which appear to depend on inoculations points with no uncertainty to the advisability of keeping a whole skin. The "verminous person" has assumed an importance in relation to the public health which the Legislature has already recognised, while the "tramp" with his special liability to small-pox is one to whom the anti-vaccinationist is likely to discover a "conscientious objection." The special liability of the "tramp" to suffer from small-pox—if such is really the case—seems to offer a field of investigation well worthy of being methodically explored.

There are other diseases more or less suspected of being soil diseases, but the facts are at present too few to make any discussion profitable. These are yellow fever, beri-beri, swine fever (*undoubtedly propagated by fouling of the surface* soil), cancer (?), thread worms, hydatids, and ankylostomum duodenale. Malignant œdema is an infective disease of wounds undoubtedly caused by a ubiquitous anaerobic saprophyte which occasionally manages to grow in the cellular tissue and to generate gas (CO_2, H, SH_2, CH_4) therein.

ABSTRACT OF THE

Lettsomian Lectures

ON

SOME OF THE CLINICAL ASPECTS OF GRANULAR KIDNEY.

Delivered before the Medical Society of London

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL, &C.

LECTURE II.[1]

Delivered on Feb. 20th, 1899.

ALBUMINURIA.

GENTLEMEN,—Of albuminuria in granular kidney it is not necessary to say much. We know that it is usually small in amount and that it is not constantly present. It may be found at special times only or may be absent for irregular periods, and it might therefore be described as cyclical or intermittent respectively. It may be absent for long periods—even, it is said, altogether—though this is hard to prove. Given a clear case of granular kidney these variations in the albuminuria do not cause surprise but clinically the question often presents itself in a somewhat different form. In a given case albuminuria may be the chief symptom. We have then to decide whether granular kidney is the cause or not. It often happens that the evidence is not conclusive for the patient appears to be in ordinary conditions of health. We are thus introduced to a problem of very great difficulty which, in spite of the attention which it has in recent years attracted, is still far from being settled—viz., that of so-called physiological or functional albuminuria.

The forms of albuminuria may be arranged into five groups:—

Albuminuria	Prerenal	1. Obvious cause—e.g., morbus cordis, fevers, &c.	
	Renal	2. No obvious cause	Physiological.
		3. No evident renal disease	
		4. Evident renal disease.	
	Postrenal	5. From urinary passages, &c., generative organs, vagina (accidental).	

Experimentally albuminuria has been produced in perfectly healthy persons by excessively albuminous diet, by violent muscular exercise, by cold bathing and exposure to cold; but even then it is probably not capable of being produced in every person or at any rate not with equal ease, so that even in such cases some other factor is necessary. Again, in an apparently healthy person albumin may be found occasionally present under certain circumstances—as for instance on rising in the morning or after food—and the albuminuria has then been called postural, dietetic, cyclical, or intermittent respectively. Intermissions or variations in the occurrence of albuminuria are no evidence that there is no disease of the kidneys. Admitting all these exceptions, there remains a group of cases in which albuminuria is present with apparently nothing whatever in the previous history or the actual condition of the patient to explain it. The choice of a term by which these cases can best be described is difficult. It is unfortunate that so many terms have been used which do no more than describe the special circumstance under which the albuminuria appears. Latent albuminuria is perhaps the term to which least objection can be raised, but it is often not so much latent as overlooked. Albuminuria in the apparently healthy seems to me on the whole to be the least objectionable term to use and to state the facts best.

The statements made by different observers as to the frequency with which albuminuria occurs in the apparently healthy vary greatly. Variations so considerable in observations made by equally competent observers show that there must be a fallacy somewhere and it may lie in the fact that different sets of cases have been observed or different tests employed. Looking broadly at the figures given by the different authors these facts are evident—(1) that the majority of observations upon which the statements are based have been made upon children and adolescents and (2) those almost entirely of the male sex, and (3) that the higher percentages have been obtained by including cases in which very minute traces of albumin were found by the most delicate tests.

Roughly speaking, the cases thus group themselves into two periods—(1) those before the age of 25 years and (2) *those after 25 years.*

There are many forms of albumin; but we need only consider two forms: (1) serum albumin, which for our purpose will also include serum globulin; and (2) nucleo-albumin, a mucin-like body which has been till lately confused with mucin. It is by reckoning nucleo-albumin in with serum-albumin that the high percentages of albuminuria have been obtained.

There is no single test upon which reliance can be placed to distinguish absolutely between nucleo-albumin and serum-albumin, but the series of tests systematically used in order will suffice to make the distinction quite clearly in most cases. Desiring to form my own opinion upon this question I asked Mr. Levison to undertake some observations for me. He examined 336 healthy persons, of whom 108 were young soldiers; the rest were hospital convalescents. A proteid reaction of some kind was obtained in 136, or 40·47 per cent., and of this serum-albumin occurred in 22·02 per cent. and nucleo-albumin in 18·05 per cent. The amount of albumin in all cases was extremely small and probably in half the cases would have been overlooked in the ordinary methods of examination. The largest amount in these series was not more than would give a ring of one to two *millimetres in thickness* with nitric acid. Nucleo-albumin was found alone in nearly one-half of the cases, 18·44 per cent., and this was the same in both the groups—i.e., before 25 years of age as well as after 25 years. No clinical difference could be detected between the cases with serum-albumin and those with nucleo-albumin. These observations show that the ordinary statements made as to the great frequency of albuminuria in apparently healthy persons *is not overstated* if all those cases be included in which *there is the minutest* possible trace evident only on careful examination, but inasmuch as in most of these cases, probably one-half, the trace is so small that it can only be detected with great care when specially looked for the contrast between these results and the general impression obtained from ordinary clinical experience is not so great as at first sight it appears to be.

It is also evident, as I have already stated, that the conclusions drawn as to the frequency of albuminuria in one age-period must not be applied without due allowance to any other age-period and that speaking generally the significance is entirely different before 25 and after 25 years of age. What is required is a systematic series of observations in which the same carefully-selected tests have been employed and a sufficient number of cases of the one sex and of the other examined at the different age-periods: (1) in infants up to the age of *five years*; (2) in young children of from five to 10 years of age; (3) in boys or girls of from 10 to 18 years of age—i.e., the school age; (4) in young adolescents *of from 18 to 25 years of age*; (5) in young adults of from 25 to 35 years of age; (6) in the middle period of life—i.e., from 35 to 50 years of age; and (7) in the later periods *of life, over 50 years of age.* Of albuminuria in infancy and early childhood we have not much information. Albuminuria is said to be less frequent up to the age of 10 years. For the period from 10 to 18 years statistics abound and show the extraordinary frequency of albuminuria. Although the amount of albumin is usually small it may be considerable. It has been suggested that the presence of albuminuria at these ages is due to the active development of the sexual organs and probably also to the presence in the urine of discharges derived from these organs and that the form of albumin is generally nucleo-albumin. The albumin is, however, generally serum-albumin and not nucleo-albumin and there is no proof that nucleo-albumin is derived from the urinary passages and not from the kidney. Nor is there any proof that masturbation is a predisposing cause; indeed, what evidence there is is against it.

In young adolescents of from 18 to 25 years of age it is upon cases of this period that most of the statements as to physiological albuminuria in adults are based. Most of the observations have been made upon young soldiers. The 108 young soldiers whom Mr. Levison examined ranged from 17 to 27 years of age; but of these only eight were above 25 years of age. A proteid reaction of some kind was found in 51 cases (47·25 per cent.). This was due to serum-albumin in 30 cases (27·75 per cent.) and to nucleo-albumin in 21 cases (19·50 per cent.). The effect of exercise is well shown; thus morning drill considerably increased the total frequency of albuminuria but made no difference in the relative frequency in the two kinds of albumin.

---

[1] Lecture I. was delivered on Feb. 6th and published in THE LANCET of Feb. 11th, 1899, and Lecture III. will be delivered on March 6th, 1899.

With regard to young adults of from 25 to 30 years of age I find that at the Provident Clerks Life Assurance Association in the course of the five years, 1893 to 1898, 7950 policies came before the office. Out of this number 25 cases were found to have albumin in the urine. This was a percentage well under one, actually of 0·55. At another office for the period of 10 years the number of applicants below 30 years of age was, roughly speaking, about 750, and out of these seven only were deferred or rejected on the ground of albuminuria. This gives a percentage of nearly one. No doubt more precise examination would have raised this percentage somewhat; still I think the facts are sufficient to show that at this age-period albuminuria is very infrequent and probably stands at its lowest point in life.

After 30 years of age there are a great many figures to show the general frequency of albuminuria for all ages during the insurance period, but they tell us little of what we really want to know—viz., the relative prevalence of albuminuria at the different age-periods throughout adult life. With these we may compare Mr. Levison's figures which yield a much higher average percentage—40 per cent. The difference in results is evidently due to the different tests employed. It would greatly simplify matters if we could agree upon a standard test, and the best in my opinion would be Heller's. An amount of albumin which cannot be shown by Heller's test may *quâ* albumin be disregarded clinically.

Latent albuminuria—i.e., in the apparently healthy, apart from its scientific interest, has a practical bearing in boyhood as affecting the school career, in young men as affecting the chance of appointments, and in adult life as affecting insurance. In considering the significance of albuminuria it will be well to retain the division into two groups, before and after 25 years of age, as we have hitherto done.

I. Significance in boys and adolescents.—Albuminuria is common during the period of growth and immaturity and becomes less frequent when development is approaching completion. The question arises whether we can connect these two facts together. I think we probably may. Assuming that during the period of growth all the tissues of the body are in a condition of instability and immaturity it is easy to suppose that very slight causes might disturb their balance and thus in the case of the kidneys albumin might appear in the urine as the result of causes which would have no effect upon the fully developed or adult organism or organ. What the clinical significance of this albuminuria in childhood and adolescence is can only be determined by clinical observation, by carefully investigating the cases at the time and watching them over a long period. Now, as regards the boys in whom albuminuria is found they appear to fall into at least two groups. In one the child appears to be robust and healthy, has a rigid artery and a high tension; these are the cases which Dr. Clement Dukes has recorded as being so frequently met with in schoolboys. In the other the children are not robust and healthy, but are feeble and pale, and in them the tension is low and the artery is not thickened. These two groups probably indicate not only different conditions but different prognoses. In no case is the albuminuria, strictly speaking, physiological; it is always pathological, though not necessarily renal. What we require to know is the course which these cases run in after-life. If albuminuria is so common in youth and adolescence and becomes so much less frequent in early adult life it follows that many of the cases have no very serious significance—in other words, that they get well. This, indeed, we also know from direct observation. Yet with those who have most experience there is evidently still some lurking doubt about the ultimate result in not a few instances. Granting that many, perhaps the majority, ultimately recover there remains another group in which the patients continue to pass albumin for many years and yet remain in good health and a third in which signs of renal disease ultimately develop. Making all allowance for exceptional cases such as these the significance of albuminuria in early life must for the present still remain doubtful.

II. Significance after 25 years of age—i.e., in adult life.—This is important in relation to life insurance. Before 25 years of age many cases may be curable; after 25 years of age the chances of renal disease increase rapidly. Conclusions drawn from cases under 25 years cannot be applied without consideration to cases over 25 years. There is a great difference of opinion professionally as to the significance and importance of the traces of albumin met with in otherwise apparently healthy persons applying for insurance and I think there is also much difference in practice. It would be important, therefore, to trace these cases in order to ascertain what becomes of them in after-life. In some instances this has been done. Thus, in Washbourn's series, out of 1070 cases 38 had albuminuria—that is to say, 3·55 per cent. Of these 38 cases 18 were traced; out of 18 cases 6 developed renal disease for certain and five more probably, giving a percentage of not less than 33 and possibly of 60. Washbourn calculated that the mortality-rate among these cases for the age was 17·54 per cent.—that is to say, it was nearly double the normal average. Munn found that out of 25 cases one died within the year following the examination, and four more died during the subsequent three years, while in all the rest the health had obviously deteriorated. In another series of 6400 adults examined between the years 1877 and 1893, 454 cases of albuminuria were found. Of 137 cases among these in which the urine was examined microscopically casts were found in 31—i.e., in about 23 per cent. Thus in round numbers albumin occurred in about 7 per cent. of all apparently healthy adults, and the probability of finding casts in the urine associated with albumin was about one in four. For the first eight years or so nearly all the cases were traced and the record is remarkably complete; after this many apparently were lost sight of. During those eight years the total mortality in cases under 40 years of age was 17 per cent. and in cases over 40 years of age 30 per cent.—a very considerable death-rate for presumably healthy lives. Evidently therefore the albuminuria largely increased the risk. In this class, taking eight years also, the mortality was still higher—viz., 20 per cent. and 50 per cent. respectively.

The following table has been calculated out for me by an actuary friend to show approximately as far as the figures permit the difference in mortality compared with healthy males, and to make the result more obvious they have been taken for differences of two years of age.

Ages attained *	Rate of following year.		Ages attained.	Rate of following year.	
	Rate from figures	Normal rate		Rate from figures.	Normal rate.
30	—	—	50½	3·70	1·97
32	1·56	1·06	52½	2·64	2·20
34	3·27	1·11	54½	3·74	2·43
36	3·33	1·15	56½	7·13	2·60

* Starting with an average of those given and assuming uniform increase for eight years.

Without laying any stress upon the actual figures these calculations show how largely the presence of albuminuria raises the mortality as well in those below 40 as in those above. We must conclude, therefore, that for the ages at which life insurances are generally effected—i.e., from 35 years upwards—the presence of even a trace of albumin in the urine is of considerable significance. It is more and more likely to mean disease as age advances, and therefore the risk to the office continually increases. Even at the earlier periods, from 25 to 35 years, it is a question whether these lives should be accepted even with a considerable addition, owing to the difficulty of excluding the commencement of granular kidney. Rabagliati threw his conclusions into the following form: (1) over 40 years of age reject; (2) under 40 years of age load heavily; and (3) in young adults rate up moderately. With the first recommendation I entirely concur. The second is necessary, but the loading might be prohibitive and tantamount to rejection for any age over 30 years. In respect of the third between 25 and 30 years there would have to be a fairly heavy loading, but between 18 and 25 years many cases could be safely accepted without any great risk. Each [illegible] this kind, however, [illegible] be[illegible] [illegible]ered on its [illegible] minuria is [illegible] [illegible]ered, [illegible] may be, and just as a diagnosis should not be made on a single physical sign, neither should a life be rejected on a single physical sign. At each age there may be innocent and harmful albuminuria, and it is the business of the physician to distinguish if possible between them.

The general conclusions to which these considerations lead are these: that the so-called physiological albuminuria is always pathological even if not always renal when the amount of albumin is more than the merest trace, and probably pathological even in these cases when there is but a *trace and no good cause obvious*. It is clear, therefore, that in every case the patient must be carefully examined, every possible cause of albuminuria searched for, and every other condition in the patient noted. If nothing else be found and the albuminuria exist alone it may possibly be harmless or accidental and of no serious significance. If renal derivatives are found as well as albumin it must be almost necessarily due to renal disease, and this is in all probability also the case even if no renal derivatives are found in patients in whom the arteries are thickened and the pulse-tension is high.

ALBUMINURIC RETINITIS.

Albuminuric retinitis brings me to another group of signs —viz., those of the later stage—for typical as albuminuric retinitis is it is of no help in the early diagnosis, as it only occurs late in the disease when the arteries are degenerate and the kidney mischief is far advanced. In its early stage and typical form albuminuric retinitis is characteristic and pathognomonic—i.e., it occurs in no other condition except that of chronic renal disease. The lesions of albuminuric retinitis consist in (1) white patches, (2) hæmorrhages, (3) exudations, and (4) inflammatory conditions. They generally develop in the order in which I have placed them. Of these changes the earliest and most characteristic are the white patches which are generally found in the region of the macula or yellow spot. The question arises whether albuminuric retinitis occurs in any other form of chronic renal disease than granular kidney. In amyloid disease I know of no instance recorded and I have not seen a case myself, but amyloid disease is rare nowadays so that my experience of it is small. In acute parenchymatous nephritis it is never seen, but it is stated to occur occasionally in chronic parenchymatous nephritis. The nature of the retinal change in both cases is the same—viz., small white patches symmetrically placed in both eyes. In their typical and favourite form they are arranged in a radiating *fashion around the yellow spot, like spokes in a wheel.* Then they are usually found in both eyes and are remarkably symmetrical in position. In very early stages they may be so minute as to be easily overlooked. The white patches may for a long time be the only lesion visible if we disregard for the present certain changes in the vessels which are probably still earlier and which will be referred to later.

Hæmorrhages generally occur at a later period. They are minute and flame shaped if seated in the upper layers of the retina, but if in the deeper layers they are larger and less regular, sometimes they are also numerous round about the yellow spot, but at other times they are scattered widely over the fundus; when they are of considerable size they naturally interfere seriously with vision. There is nothing characteristic about them, for similar hæmorrhages may be seen in grave anæmia and in optic neuritis of other origin. They may in time be absorbed, sometimes without leaving any trace behind. When exudations occur the appearances present a close resemblance to other forms of optic neuritis; thus the vessels may be covered with effusion, the discs be swollen, and the edges be indistinct and frayed out; yet even in the most extreme cases there is generally something in the appearance of the fundus to suggest the cause of the trouble. Early as the white patches are they are preceded and result from still earlier changes in the vessels. The lesions in the vessels have been carefully studied by Brailey and Edmunds, and are briefly described by them as obliterative arteritis leading to inflammatory degeneration of the structures supplied. The ophthalmoscopic appearances connected with these changes have been admirably described by Mr. Marcus Gunn. He thus connects them with the changes in the vessels: narrowness and irregular size of the vessels is explained by the thickening and by the diminished lumen; the tortuosity by the increased rigidity and loss of elasticity; the increased light reflex and the bright central streak by the fibro-hyaline change; and the distension of the veins by the great thickening and resistance of the artery as it lies upon them. The difficulty of circulation leads to the general œdema; the progressive disease of the vessel to hæmorrhage; and the defective nutrition of the nerve-cells and fibres to the white patches. The radiating arrangement, the white patches round the yellow spot, he refers to the radiating folds into which the retina in that region is thrown when œdema occurs there. The changes described, Gunn states, begin to be seen usually between the ages of 40 and 50 years, but they are not due to old age—i.e., to atheroma—for this does not produce them, but they *may occur much earlier in life* than this. The changes of which Gunn gives so good a description are really the early changes of granular kidney. It is obvious that the degenerative changes described, though generally bilateral and more or less symmetrical, might be unilateral, so that a high degree of albuminuric retinitis might be found in one eye while the other remained perfectly normal or nearly so.

The vascular changes of granular kidney are of great importance in relation to various hæmorrhagic affections of the eye—e.g., hæmorrhagic retinitis and hæmorrhagic glaucoma. Hæmorrhage occasionally occurs behind the eyeball in the orbital chamber. Spontaneous hæmorrhage under the conjunctiva, just as occurs in aged people as the result of atheroma, is not at all uncommon. Detached retina is an interesting but not altogether rare phenomenon in granular kidney. It is in most cases due to an effusion of serum beneath the retina and not, as might be expected, of blood. I have seen hæmorrhagic detachment of the retina but it is a rare affection. The early lesions of albuminuric retinitis produce no defect of vision and even in the later stages it is very remarkable how extreme the eye changes may be without a complaint being made of impairment of sight. Routine examination with the ophthalmoscope will often discover albuminuric retinitis when it is not expected and will make a diagnosis clear which may till then have been obscure. *As* a rule we may say that when patients complain of defect of vision the albuminuric retinitis is already very *far* advanced. When the vision once begins to fail it fails rapidly.

Amblyopia is often said to be a common symptom of uræmia and is usually regarded as either of peripheral origin in the retina or central in the brain or special ganglion. Most of these statements date from a time when the ophthalmoscope was not systematically used. Of toxic retinal amblyopia we know little or nothing, for most of the cases are associated with very definite lesions in the retina visible with the ophthalmoscope. The amblyopia of central origin—i.e., non-retinal—is often associated with other symptoms—e.g., hemiplegia. In such cases the amblyopia is also due to lesions of an organic kind. It is not rare when a patient dies from uræmia to find the symptoms which appeared to be merely toxic or functional explained by an organic lesion in the brain—viz., small hæmorrhages. In cases of amblyopia in which the defect of sight persists after the uræmic attack is past we must presume that there has been an organic lesion. In cases of toxic amblyopia recovery ought to take place in the course of a few hours or less, though instances are recorded in which recovery has been sudden and complete even after four days. Some clue as to place of origin of the amblyopia may be given by the condition of the pupil. It would be an interesting question to ascertain in what proportion of cases *of granular kidney* albuminuric retinitis occurs, but that is impossible, for we have not yet the figures upon which a conclusion could be based. I should say that in most cases of granular kidney, if the patients live long enough, albuminuric retinitis does ultimately develop, but a *large number* of patients with granular kidney die from other causes—e.g., from hæmorrhage in the brain, and so do not reach the state in which albuminuric retinitis develops. Albuminuric retinitis is said sometimes to disappear. On this point, I think, some caution must be exercised. Hæmorrhage, of course, may be absorbed and may disappear, whether due to granular kidney or not, but I have never seen the glistening white patches of granular kidney disappear, though instances are recorded by good observers. It is, of course, possible where eye changes occur in the course of chronic parenchymatous nephritis that if the primary disease gets well the eye changes also may disappear; but this is not so in granular kidney. The significance of albuminuric retinitis is always grave, not only in respect of sight but also of life. The duration of albuminuric retinitis, or of life after its appearance, it is not possible to *determine* accurately. Speaking generally, the duration of life after albuminuric retinitis has been discovered is short Where the patients are in a condition to take the best care of themselves life may be prolonged for some time, but such cases are quite exceptional, and, speaking generally, when albuminuric retinitis is found the patients have not many months to live

ON TWO NEW MODIFICATIONS OF ENTERORRHAPHY,

WITH A SHORT REVIEW OF THE SUBJECT

BY ALEXANDER MACLENNAN, M B GLASG, L M ROTUNDA

IS it a proof of imperfection in our present methods of intestinal anastomoses or enterorrhaphy that almost every day sees another plan added to those already described, or is it simply due to the attractiveness and fascination of the subject? There can be little doubt that modern operators continue to employ various methods, many of them their own or their own modifications of recognised and classical operations This divergence of procedure shows at least that no one method is so superior as to hold the field to the exclusion of others The earlier methods have had time to be tested and after all is said and done many modern operators[1] prefer the simple stitch of Lembert (a single line of sutures), the Czerny Lembert[2] (a double line of sutures), or the Czerny method as modified by Wölfler[3] These methods have been tested by experience and a striking proof of their efficacy is the fact that one or other of them is resorted to when a would be new method fails when attempted on the intestine of an animal Bier[4] thinks the Lembert suture excellent and he has employed it successfully many times Edmunds and Ballance[5] in an experimental research into the relative merits of the various recognised methods have found that the Czerny suture is apt to be followed by a diaphragmatic ring projecting as a ledge into the bowel and producing a degree of annular stricture This result probably arises from inserting the stitches too far from the cut margin

The great drawback to these operations is, however the time involved, while they require a considerable degree of manipulative skill It would be quite impossible even to mention all the various operations suggested for intestinal anastomosis without writing a large treatise on the subject For the purpose of this paper it will suffice to mention some of the leading types

By Senn s[6] method of lateral anastomosis with the aid of decalcified bone plates an immense number of experiments has been done and the testimony in its favour is considerable, while some observers[7] have enthusiastically advocated its adoption Baracz[8] in an exhaustive paper on this subject recommends it strongly and holds that Senn's invention is a great advance in intestinal surgery, but he states that perhaps where there is great relative disproportion between the ends to be united (as happens often in cases of strangulation) Senn s method of lateral anastomosis is not so suitable Reichel[9] however, thinks it difficult to avoid perforating the gut while sewing over the plates and also that the blind ends are apt to facilitate the formation of concretions which may eventually obstruct the new lumen Frey[10] mentions that sloughing may take place over the borders of the plates

Senn's method has been modified by numerous surgeons the chief alteration consisting in the substitution for bone plates of such substances as catgut (made into mats and rings),[11] raw potato[12] beetroot and turnip,[13] fresh ox hide and segmented rubber plates,[14] or segmented rubber rings[15] held together by strands of cat gut Jessett[16] in his work, however, states that bone plates are much the best Littlewood[17] and Jessett[18] join the two plates by means of a tube of bone and state that there is less chance of the two corresponding openings in the bowel becoming displaced (Senn has also modified Jobert's invagination method and his operation is usually described in the text-books)

There does not seem to be much published disapprobation of Senn's lateral method (with the exception of Reichel s)[19] but one rarely sees the operation performed Is this due to the complicated appearance of the description or to the general dislike of surgeons[20] to the employment of mechanical contrivances which are perfect only in theory? Operators like to see everything safe and prefer to take all the responsibility rather than depend on any instrument Anastomosis by Senn s method can be carried out fairly quickly, but the stitching which is essential naturally occupies some time The bone plates are somewhat bulky and must be to some extent a disturbing element in the healing process, while rings and mats of catgut are absorbed too quickly[21] It does seem strange that the ends of the intestine should be carefully sewn up and two new openings made all in order to allow of the use of the bone plates

The methods of lateral anastomosis of Abbe[22] and Halsted[23] involve even more sewing Halsted's method however, receives the support of Edmunds and Ballance[24] and of Greig Smith and Jessett[25]

Maunsell s[26] method, perhaps the best of the end to-end unions where simple suturing is resorted to, is generally conceded as being specially applicable to cases of intussusception It gives a perfect mucous "first line of defence" The extra longitudinal incision made to enable the suturing to be performed from within is however objectionable[27] The same fault can be found with Ullmann s[28] method which is an improved type of Maunsell s operation Maunsell s operation has also been modified by Jessett, Barker, and Bier[29] According to Edmunds and Ballance there is no resulting ring of contraction and they state that it is the best method for end to-end junctions

Of the many methods utilising the principle of invagination those of Nicoll[30] Paul[31] Robinson[32] and Senn are types Paul and Robinson employ bone or rubber tubes while Senn and Nicoll discard them The bone tubes &c, used by those operators are too long and there is in Paul's method the risk of invagination beginning in front of the tube and so producing an artificial intussusception The treatment of the bowel in Robinson s method is too rough and must greatly interfere with the blood supply of the parts which are left to unite Its principle has been described independently by Jessett Nicoll and Skelly[33]

Bishop s[34] method principally brought forward to avoid an annular contraction ring, is difficult and tedious[35] to perform

[35] [illegible]

Mayo Robson[36] has recommended and used decalcified bone bobbins over which the intestine is sutured. In desperate cases where the saving of time is of paramount importance he does not mind risking only a single line of deep sutures.

Allingham[37] has modified the bobbins and Hayes[38] is responsible for yet another variation. There must, however, be considerable pressure of the bowel between the resisting bobbin and the operator's fingers during the process of suturing. Harrison Cripps[39] thinks the bobbins are apt to become impacted and also to cause necrosis of the intestine. Edmunds and Ballance agree with him and also with Bidwell who asserts that bobbins tend to obstruct the lumen. To overcome this objection Downes[40] sutures over a ring and subsequently makes an incision in the gut in order to remove this ring. Landerer[41] of Leipsic uses potato or turnip bobbins.

Probably the greatest step forward[42] has been made by Murphy[43] by the introduction of his metallic button, though one writer describes it as the "most popular ...... most dangerous" button.[44] The general distrust of all instruments delayed for some time its adoption both in this country and on the Continent, but within the last few years it has been extensively employed and there is a corresponding mass of literature on the subject. By this time probably all the merits and demerits of the instrument have been fully discussed and chronicled. The button being of metal is heavy, and Abbe[45] reports a case where its weight caused the intestine to kink with subsequent obstruction. It is generally admitted that it is prone to cause ulceration,[46] especially if too large a button be employed. Many of the instruments now in the market are quite unreliable and so faultily made that they do not bite equally all round.[47] In this way the button may eventually come to hang loose in the lumen like the tongue of a bell. To close the two valves firmly enough so as to get the quickest and best union pressure has to be transmitted through the intestine and this might be brought forward as an objection. Murphy did not intend that a Lembert suture should be used to complete the operation, and, indeed, Marwendel[48] has demonstrated a case where this superadded "safety" suture was the cause of a perforation. Orzet[49] also thinks it not only unnecessary but dangerous to employ any such suture over the Murphy button. Bishop[50] in bringing forward the merits of his internal suture states that adhesions to the omentum or surrounding the seat of union almost always follow enterorrhaphy, and he affirms that external sutures increase this tendency. Graff,[51] on the other hand, thinks the Lembert suture safer and always adds it. To put in this suture requires more time and necessitates more manipulation of the intestine-covered button. In gastric operations Jonnesco[52] thinks it a drawback that the incision in the stomach to admit the button requires to be so much larger than the available lumen of the new passage. A drawback of some moment seems to be the narrowness of the lumen of the instrument relative to its circumference.[53] Graff[54] cites a case of Duvivier[55] where obstruction was produced and he mentions two other cases where the passage through the button became completely occluded by intestinal contents.[56] This he states as likely to occur in the colon and the lower reaches of the ileum. He thinks a tendency to enlarge the button to get a larger lumen would accentuate its *action as a foreign body*. Notwithstanding these defects Graff gives the button a whole-hearted recommendation and thinks it the best *means* at our disposal. He cites cases of gastric operations where the button has fallen back into the stomach and remained there during life without causing symptoms. On post-mortem examination no change was found to have followed its presence in that organ. Kümmel[57] has also observed the backward fall of the button into the stomach, and Allis[58] reports a case were the button remained 16 months in that viscus. If, however, such a button has difficulty in passing through the new exit from the stomach it will meet with a similar obstacle at the ileo-cæcal valve. Most surgeons do not feel quite free from anxiety until the button passes *per viam naturalem*. Graff warns operators that the use of the Murphy's button requires practice and that if the two valves are too firmly pressed together sloughing occurs too soon, while if not firmly enough good union does not take place or there may be leakage. Regarding the question of secondary contraction at the seat of junction Bretano[59] found that in 398 collected cases it occurred only three times. Frank,[60] in demonstrating his method which acts much in the same way, denies the possibility of the occurrence of secondary stricture and probably such a tendency *is* very remote. Naturally there are a great and rapidly increasing number of modifications of Murphy's button.

Chaput's[61] latest design is lighter (and less expensive), as effective, and has a relatively larger lumen, while its mechanism is simpler.

Boari[62] has made the tubal portion of the button of metal while the remainder consists of bone only partially decalcified. This instrument he *affirms* does not tend to *remain* for indefinite periods in the abdomen but only long enough for its purpose.

Martin Gil[63] has described the manner of use of a button of decalcified ivory.

Frank[64] has described and demonstrated his modification which consists of two solid end-pieces of decalcified bone joined by a rubber tube, sufficiently short to ensure their close apposition and to prevent their separation except by stretching the tube. The action of this appliance is the same as Murphy's button. It is light and cannot certainly remain long in the bowel, but the separation of the valves is difficult and requires such force that damage[65] may result to the intestine while the available lumen is small. It is not to be recommended for gastric operations.[66]

Jackson Clarke,[67] from experiments on the cadaver, gives an account of a new method which from the description promises well. His adjustment of the two rings over his rubber bobbin might in some circumstances require an amount of force, the employment of which would be injudicious. The rubber mechanism must tend to constitute a considerable foreign body.

So far, then, there seem to be objections to every method and no one method can be said to be of universal application. Different inventions may *adapt* themselves to different conditions and certainly the science of surgery is not the poorer because of the multiplicity of procedures for intestinal anastomoses. Edmunds and Ballance in their investigation already referred to attempted to solve the comparative value of the many methods in vogue. As a result they advocate Maunsell's method for end-to-end and Halsted's for lateral anastomosis. The conclusions arrived at from their investigation might be accepted as accurate were it not that the conditions found in animals differ so greatly *from* those in man.

For the methods about to be described perfection cannot be claimed, yet the suggestions given may in some circumstances be found applicable and may add to the wealth of resource already at the command of the surgeon. It had been intended to operate on dogs but the thick muscular and mucous coats which rather facilitate suturing experiments almost prohibit those by a method of invagination The same objection applies to the cat [68] In the rabbit the relative conditions more resemble the human though, of course, the intestine is very small On account of the thinness of the intestinal wall the rabbit cannot overcome any resistance and is very liable to ileus [69] The upper part of the jejunum is very friable and readily tears Any operation successful in such an intestine will certainly be much more so in the human subject [70] Both of the following methods utilise the invagination principle The first has the minimum of stitching while the second has none at all Clamping of the intestine previously to union was not resorted to

I (*A*) *Treatment of the proximal end of the intestine* (It is essential to differentiate between the proximal and distal extremities, as in two cases death ensued from mistaking the distal for the proximal) —Into the proximal end of the gut is inserted a short, light, decalcified bone tube (Fig 1) of a diameter somewhat less than that of the intestine in its normal condition The use of too large a tube adds difficulty to the technique and perpetuates a distension of the gut which is detrimental. In the case of the rabbit the length of the bone tube employed was about twice that of the diameter, but for operations on a larger gut the tube can be greatly shortened so that the length does not exceed the diameter The thickness of the tube need only be sufficient to give it stability and allow of the grooving Rubber, potato, or turnip tubing might of course answer the purpose equally as well as decalcified bone The tube is then fixed in position by ligaturing the intestine firmly into groove A which is not so deep as B (Fig 2)

FIG 1

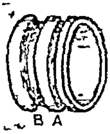

FIG 2

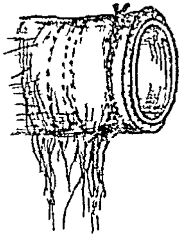

FIG 3

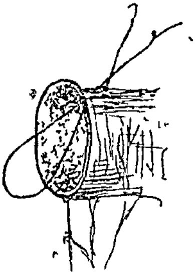

B The treatment of the distal end —About from one quarter of an inch to one third of an inch (in the rabbit not more than one-quarter of an inch) from the edge, at a point opposite the mesenteric attachment the two ends of a loop of silkworm gut (threaded on a needle) or of silver wire are passed through the entire thickness of the bowel, as in Fig 3 The loop is then drawn within the lumen of the gut and is made to distend by a backward push the wall of the intestine, as shown in Fig 4 When so distended the part of the intestine outside the loop allows itself to be easily involuted into the intestine through the distending ring (Fig 5) Into this gut lined ring is next inserted (as in Fig 6) the proximal end till the wire or silkworm gut comes to lie round the groove B (Fig 1) in the bone tube The wire or gut is now firmly tied By this means the invaginated layer of the distal end together with the layer covering the bone tube are firmly compressed into the groove The ligature is then cut short and the small opening through

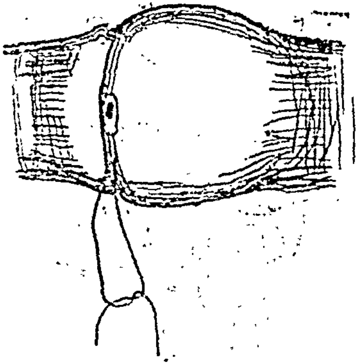
which it passed is closed by a purse-string suture as in Fig. 7. The mesentery is then united and the loop is returned to the abdomen.

FIG. 7.



II.—This is a modification of the first method. The treatment of the proximal extremity is the same as in that method. The difference lies in the employment, instead of wire or gut, of a round rubber ring which is inserted into the distal end about from one-quarter of an inch to one-half of an inch from its free margin (Fig. 8). The ring should be of such a diameter as to fit closely into the groove B (Fig. 1) of the naked bone tube and of sufficient strength to grasp it firmly when there are two layers of intestine interposed. The free one-quarter of an inch to one-half of an inch of intestine is then invaginated into the ring and is kept in position by means of three or four hooks (Fig. 9). These are also used to keep the gut-lined ring sufficiently distended while the proximal end is being inserted. The hooks are removed when the insertion has proceeded far enough to allow the contracting ring to press the intestine into the groove B (Fig. 1) in the bone tube. The mesentery is then united and the loop of intestine is returned to the abdomen. To avoid injury of the intestine the hooks, though sharply pointed, must curve only sufficiently to surround the ring and perforate alone the inner layer of bowel as illustrated in Fig. 10. When dealing with a larger bowel than a rabbit's blunt hooks would answer the purpose.

FIG. 8.

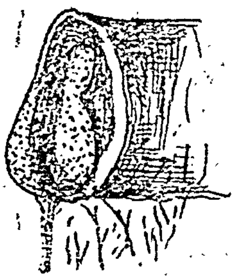


FIG. 9.

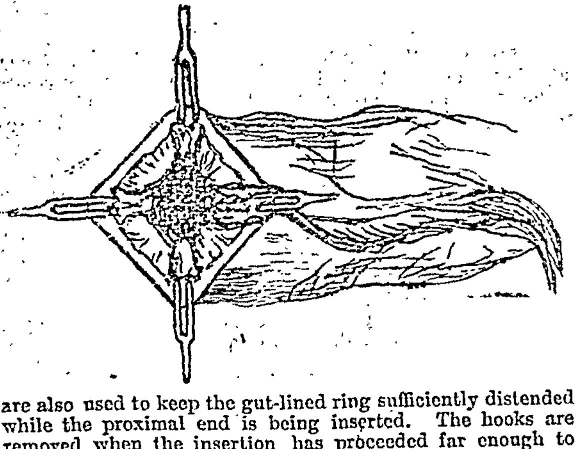
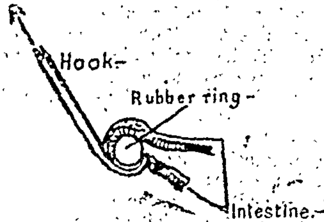


The details of the operations which I performed on each rabbit are as follows. In all cases full-sized rabbits were employed and were operated upon under ether. The wounds in each case healed by first intention. In one or two abdominal herniæ developed. None of them were "nursed" and they were allowed to take their usual food immediately after operation.

No. 1.—Laparotomy with section of the loop of the small intestine and then enterorrhaphy by the first method were performed on July 1st, 1898. The animal died on the next day. Post mortem the abdomen was greatly distended, due to distention of the stomach and of about 24 centimetres of intestine to the seat of junction. It was found that the lower or distal end of the gut had been in error invaginated into the upper and the minute bone tube was displaced laterally while its lumen was stopped with intestinal contents. On cutting out the junction and testing with a stream of water under slight pressure the union was found not to leak.

FIG. 10.



No. 2.—This was a laparotomy with section and junction by the first method performed on July 4th, 1898. The appendix was injured by mistake and part had to be excised. The stump would not close satisfactorily so it was stitched to the abdominal wound. This animal had previously (on May 28th) had a thyroidectomy performed on it without showing any symptoms of strumipriva. It was the only rabbit available at the time. On July 8th the animal was found dead. Post-mortem examination showed the stomach and intestines to be generally distended. There were no general adhesions, but slight adhesions round the junction. There was no obstruction and no leakage with the water test. The bone tube was still in position. The stump of the appendix was free in the abdominal cavity and death was obviously due to this.

No. 3.—(*a*) On July 9th, 1898, a laparotomy operation by the first method was performed. (*b*) On August 2nd, 1898, the abdomen was reopened (abdominal hernia). The peritoneum was healthy. The operation was by the second method. The animal died from excess of ether during closure of the abdomen. A post-mortem examination was made on the same day. The first junction (the operation of July 9th), 40 centimetres from the pylorus, had healed and was adherent to the intestine above and below—the whole forming an S-shaped loop. (Coccidiosis of the liver with hydatids of the mesentery were present.)

No. 4.—(*a*) This was a laparotomy by the first method performed on July 9th, 1898. The intestine was friable. Two Lembert sutures had to be put in as the gut tore while the ligature was being adjusted (these sutures passed from the distal to the proximal intestine and brought a covering of peritoneum over the rather large perforation). (*b*) On August 5th the abdomen was reopened. The peritoneum was healthy. The second method was employed and was performed with the greatest ease. On August 7th the animal died. Post mortem there was no peritonitis, but the stomach and intestine were distended. The first junction, 40 centimetres from the pylorus, was one of perfect union. There were light adhesions to the intestine on one side only. The second junction was higher up. Death was due to the lower end being invaginated by mistake into the upper.

No. 5.—(*a*) This was a laparotomy operation by the second method carried out on August 5th, 1898. The intestine (evidently the upper part of the jejunum as the contents were semi-digested only) was very friable; it repeatedly tore and the junction had to be cut out several times as the bone tube was slightly too large. The junction was eventually performed with the greatest ease when a smaller tube was used. (*b*) On August 25th the abdomen was reopened (abdominal hernia was present). The peritoneum was healthy. The second method was easily performed for the second time. On Oct. 1st the animal was killed. The following report of the post-mortem condition was kindly sent to me by Dr. Ludwig Pick, Director of the

"Laboratorium der Professor Dr. Landau'schen Frauenklinik," Berlin: "The seat of the first operation was situated one and a half inches below that of the second. While the place of the first operation was found with difficulty and showed only a very slight constriction the place of the second felt more solid, seemed retracted, and was surrounded by various adhesions with visceral and parietal peritoneum. The gut was permeable at both places equally well without a sign of stenosis."

From the above-mentioned experiments I would draw attention to the danger of mistaking the distal for the proximal end in all cases where the invagination method is employed. A fatal result following this mistake has been observed by Jessett,[71] Robinson,[72] and Senn in their experiments on animals. The direction of the intestinal current before performing such an operation should always be clearly observed.

It is claimed for the method I have described that it is easy and rapid while the requisite apparatus is of the simplest and lightest description. There is the minimum of handling of the intestine and so therefore the minimum of injury. The intestine of the rabbit is so delicate that the slightest tension or pressure ruptures the blood-vessels. Operations on them, if they are to be successfully performed, require special attention to technique, while the extra freedom which might be permissible on the larger and stronger human intestine would make the adoption of this method in the latter case so much the easier.[73] A "safety" stitch over the junction is probably more dangerous than otherwise, and in the rabbit would only lead to perforation and escape of intestinal contents. The progressive nature of the pressure in the second method between the two serous surfaces at the seat of union is a further advantage. The elastic ring ensures perfect uniformity of pressure and prevents any tendency to hæmorrhage which, according to Greig Smith,[74] is excessive where the bowel is congested. Hæmorrhage after simple stitching must cause at least microscopic separation of the two surfaces to be united.

The greatest objection to all methods depending on gangrene for removal of the means of union is stated to be the liability of the gangrene to extend outwards beyond the control of the apparatus into a dangerous region. This will be all the more likely to occur when the intestine has been subjected to pressure or where the integrity of the serous surfaces has been impaired by the addition of so-called safety sutures. The bone tube being a perfect cylinder occupies the minimum of space, ensuring at the same time the maximum of lumen through which the delayed intestinal contents can readily pass into the bowel beyond. As the tube is covered with intestine it is practically not in contact with the healing line and certainly cannot by its presence influence that process at all. There is no foreign body (in the second method) other than a flexible rubber ring to be voided, and this cannot possibly give rise to obstruction, nor should trouble follow the use of silkworm gut or silver wire as in the first method. Neither operation has been utilised to affect a union of intestine with stomach, but doubtless either could be readily adapted to the special requirements of such a case.

My best thanks are due to Professor Hermann Munk, Director of the Physiological Laboratory in the Königliche Thierarzenei Hochschule of Berlin, for permission and facilities to carry out these investigations. The second operation in the last rabbit was performed in the pathological section of the laboratory of Professor Landau at his request.

Glasgow.

TAUNTON AND SOMERSET HOSPITAL.—The annual meeting of this institution was held on Feb. 9th, under the presidency of Mr. F. H. Cheetham. The financial statement showed that the income during the year amounted to £6174, against £3578 in 1897, and the total expenditure was £4310, against £4202 in the previous year. The medical report stated that 828 in-patients had been admitted, against 783 in 1897, the daily average in the hospital being 81. The out-patients numbered 3968, against 4167 in the preceding year. Colonel Welby, M.P., was elected president for the ensuing year.

THE OPERATIVE TREATMENT OF TYPHOID PERFORATION OF THE INTESTINE,

WITH A REPORT OF THREE CASES; ONE SUCCESSFUL.

By J. E. PLATT, M.S. LOND., F.R.C.S. ENG.,

SURGICAL OFFICER TO THE CANCER HOSPITAL, MANCHESTER; HONORARY SURGEON TO THE HULME DISPENSARY; LATE RESIDENT SURGICAL OFFICER TO THE MANCHESTER ROYAL INFIRMARY.

OPERATION for the relief of typhoid perforation of the intestine was first proposed by Leyden[1] in 1884 and was carried out by Mikulicz[2] in the same year, although the latter only made a diagnosis of typhoid fever from the conditions which he found after he had opened the abdomen. The first surgeon who operated for a perforation previously diagnosed was Lücke[3] in 1885. A considerable number of cases have now been reported and on the whole we may say that the results have improved during recent years. From time to time the published cases have been collected and analysed by Van Hook,[4] Abbe,[5] Monod and Vanverts,[6] Finney,[7] Gesselewitsch and Wanach,[8] and Keen.[9] Keen in January, 1898, collected 83 cases with 16 recoveries. To his list I am able to add three cases of my own and 17 published by others, giving a total of 103 cases with 21 recoveries. My own cases are as follows.

CASE 1.—A man, aged 37 years, was admitted to the Monsall Fever Hospital, Manchester, at midnight on Nov. 15th, 1898. The history given was that the illness had commenced on Nov. 5th with headache and pains in the limbs, followed on the next day by slight diarrhœa. When admitted the patient was suffering from an apparently mild attack of enteric fever. The temperature was 102° F.; the tongue was moist and coated, the abdomen was fairly soft, there were a few rose-spots, the spleen was a little enlarged to percussion but was not felt, and numerous rhonchi were to be heard on auscultation of the lungs. Widal's test gave a positive reaction. On the next day (Nov. 16th) at 8 P.M. the patient complained of sharp shooting pains below and to the right of the umbilicus; two hours later the temperature rose to 104·6°. On the 17th at 11 A.M. the patient vomited once. The abdomen was hard and distended, the tongue was dry, and the bowels were constipated. The pulse was 96 per minute, regular, of good volume, but slightly dicrotic. At 1 P.M. the liver dulness had disappeared and perforation was diagnosed. Dr Marsden, the resident medical officer, therefore sent for me to see the patient with a view to operation.

On Nov. 17th at 6 P.M., probably 22 hours after the onset of the perforation, I proceeded to operate. An incision four inches long in the right semilunar line was made. On opening the peritoneum there was an escape of gas, followed by a little feculent fluid; the intestines were greatly distended. It was necessary to eventrate a considerable portion of the small intestine before the perforation could be discovered. The perforation was about a quarter of an inch in length and was situated opposite the mesenteric attachment in a loop of ileum lying near the pelvic brim; its distance from the cæcum was not ascertained. The neighbouring coils of intestine were covered by a fair amount of dirty fibrinous lymph. There was evidence of several other ulcers in the intestine; the edges of the perforation were turned inwards and the peritoneal surfaces were united by a continuous silk suture introduced by an ordinary sewing-needle. Considerable trouble was experienced in returning the intestines to the abdomen because of their great distension. The eventrated intestines and also the peritoneal cavity were irrigated freely with hot saline solution. A rubber drainage-tube was introduced, passing down towards the pelvis, and the rest of the wound was sutured. The operation lasted

50 minutes. On the 18th and 19th the patient was fairly comfortable. The temperature varied between 98·4° and 99·8°; the discharge from the wound consisted of a little thin, yellow, slightly opalescent serum. On the 20th the abdomen was greatly distended, the tongue was dry, and there were retching and slight sickness. Some relief was obtained from an enema containing turpentine. From this date the patient progressed favourably until Dec. 2nd when there was a relapse of the fever which lasted for three weeks. The drainage-tube was removed on Nov. 30th and gauze-packing was substituted. The wound was healed on Dec. 26th.

The discharge throughout had been small in quantity. After the subsidence of the relapse the patient progressed rapidly to complete recovery. He was discharged from hospital on Jan. 20th, 1899, 64 days after the operation. He was shown at a meeting of the Manchester Medical Society on Feb. 1st and was then perfectly well with the exception of a slight tendency to bulging of the abdominal wall at the seat of operation.

CASE 2.—The patient was a male, aged 17 years, whose illness commenced on Oct. 22nd, 1898, with headache, constipation, and dizziness. Four days later he had to lay up because of abdominal pain and cough. On admission to Monsall Fever Hospital he was suffering from typhoid fever of a severe type. The abdomen was full and firm, the tongue was dry and coated, the pulse was 96, the temperature was 103·4° F., the spleen was palpable, and there was bronchitis. Until Nov. 19th there was no marked change in the patient's condition. At 4 P.M. on that day he vomited once; the abdomen was not distended but it was fairly firm and liver dulness was present. At 9 P.M. there was retching, the abdomen was distended, and there was resonance over the liver. At 11 P.M. the abdomen was more distended and was very tender and there was hiccough. The pulse was 140 per minute.

On Nov. 20th at 10 A.M., 18 hours after perforation, an incision four inches long was made in the right semilunar line. There were gas and fæces in the abdomen; the intestines were not much distended. The perforation was found at once in a loop of ileum passing from the iliac fossa into the pelvis; it was situated near the pelvic brim. An attempt was made to close the opening by a continuous suture, but the bowel-wall was so rotten that some of the loops cut out. With some difficulty the opening was closed by interrupted Lembert's sutures, its edges being turned inwards. The abdomen was washed out with hot saline solution, a drainage-tube from the wound into the pelvis was inserted, and the rest of the wound was sutured. The operation lasted 40 minutes.

After the operation the patient was much collapsed and about half an hour afterwards two pints of saline fluid were infused into the median basilic vein. He rallied somewhat for a time, but he died at 7.15 P.M. on the same day, eight and a half hours after the completion of the operation.

The necropsy showed general peritonitis, six or seven other ulcers in the ileum, and the perforation to be situated nine inches from the cæcum. The sutures were sound and the perforation was sealed.

CASE 3.—The patient was a man, aged 22 years. Illness commenced on Nov. 1st, 1898, with headache, diarrhœa, and shivering. He was admitted to Monsall Fever Hospital on Nov. 10th suffering from a severe attack of typhoid fever; he was very restless, the tongue was dry and dirty, there were rose-spots, the abdomen was tense, the spleen was felt on palpation, and there were diarrhœa and vomiting. On the 20th at 2 A.M. there were stabbing pains in the abdomen. At 1 P.M. the abdomen was distended, firm, painful, and tender; the face was drawn and pale; and there was a tympanitic area over the left lobe of the liver. At 6 P.M. liver dulness was absent. At 10.15 P.M. there was retching.

On Nov. 20th at 11.30 P.M., 19 hours after perforation, an incision in the right semilunar line four inches long was made. There were gas and about a pint of feculent fluid in the abdomen; the intestines were not much distended. The perforation was easily found in a loop of ileum situated near the pelvic brim; its edges were turned inwards and interrupted Lembert's sutures were applied. The abdomen was well flushed out with warm salt solution, a drainage-tube was inserted into the pelvis, and the rest of the wound was sutured. The operation lasted 45 minutes. The patient rallied for a time, but then sank and died on Nov. 22nd at 11.50 P.M.

At the necropsy the perforation was seen to be about nine inches from the ileo-cæcal valve. The sutures were sound. There was peritonitis which was limited to the pelvis and the right iliac region; the ascending colon and the right half of the transverse colon were distended, but the rest of the colon and the sigmoid flexure were small, empty, and contracted, with apparently a kink at the middle of the transverse colon. There was a large number of typhoid ulcers.

I have to thank Dr. Marsden for the notes of the above cases with the exception of those relating to the operations. The successful result in the first case was due just as much to his diagnostic skill and to his careful and judicious after-treatment as to the operation which was performed. In the second case it is clear that there could be but little hope of a favourable issue. The third case is interesting because although unsuccessful it shows that the peritonitis following perforation may be limited by operation even after the escape of a large amount of fæcal matter. The cause of the kinking of the transverse colon is uncertain. In Dr. Marsden's opinion it had nothing to do with the operation, and, but for its occurrence, the man would have had a fair chance of recovery.

Perforation from the point of view of operation.—From the statistics given by Fitz,[10] it would appear that intestinal perforation is the cause of death in about 6·58 per cent. of fatal cases of typhoid fever. The same writer states that perforation is most common during the second, third, and fourth weeks of the disease, the largest number of cases occurring during the third week. In the great majority of cases the perforation is situated in the ileum within two feet of the ileo-cæcal valve. In a smaller number of cases it occurs in the appendix, the cæcum, the colon, or higher up in the small intestine. In 29 out of 167 cases collected by Fitz more than one perforation was present; in 10 cases three or more ulcers had given way.

It would appear that there is no definite relation between the severity of the individual attack of fever and the occurrence of perforation. Not infrequently it is noted that perforation occurs during an attack which is apparently following a mild course, and it is in such cases that operative interference is most likely to be attended with success.

That perforation does occasionally lead to localised peritonitis, the general peritoneal cavity being shut off by adhesions, is certain, although the cases in which it has been proved beyond doubt are few in number. One such case was recently reported by Elsner.[11] The patient died from hæmorrhage some days after there had been symptoms of perforation, and at the necropsy localised peritonitis around a perforated ulcer was found, the peritoneal cavity being completely shut off. In Watson's successful operation case[12] the peritonitis was strictly limited by adhesion of the perforation to the anterior abdominal wall. (In all the other successful cases it would appear that peritonitis had spread more or less widely.) Probably in some of the localised cases peritonitis occurs first from extension of inflammation through an ulcerated but unperforated intestinal wall leading to the formation of adhesions, and perforation takes place subsequently. In the great majority of cases, however, perforation leads to a more or less diffuse peritonitis, and under such circumstances a fatal issue is almost, if not quite, inevitable. Dr. J. F. R. Gairdner[13] has collected from the clinical and pathological records of Belvidere Fever Hospital, Glasgow, 47 cases of peritonitis occurring in typhoid fever and has studied them from the point of view of operative interference. As a result of his investigation he has come to the conclusion that in 49 per cent. of the cases laparotomy would have offered a fair chance of recovery, and that in 19 per cent. of the whole number the chance would have been distinctly good. Dr. S. Phillips[14] of the London Fever Hospital, speaking at a discussion at the Royal Medical and Chirurgical Society, said that he recognised two types of perforation cases: 1. Those with tympanitic abdomen; in such cases leakage is largely prevented owing to the distension of the intestines and operation is likely to be successful. 2. Those with doughy abdomen and no striking symptoms, the patients dying from asthenia; under such circumstances extravasation occurs freely and the conditions are unfavourable to operative interference. These observations I regard as of very great value; my successful case was clearly of the first type, whilst my unsuccessful cases approached more nearly to the second type. Distension of the intestines must therefore be regarded, contrary to the statements of some writers, as rather improving than diminishing the chances of a successful operation.

[14] THE LANCET, Jan. 30th, 1897, p. 313.

Objections to the operation.—The chief objections which have been advanced are (1) the difficulties in early diagnosis of perforation, (2) the bad general condition of the patient, (3) difficulties in finding the opening, (4) the diseased condition of the walls of the gut, (5) the occasional occurrence of multiple perforations, (6) the presence of a grave peritoneal lesion, and (7) that some cases diagnosed as perforation have recovered. These objections are more apparent than real and in almost every case are sufficiently answered by pointing to the results of operation.

Into the question of diagnosis I do not propose to enter. Of the importance of early recognition of perforation there can be no doubt and hence a very great deal depends upon the skill of the physician in charge of the patient. In fever hospitals, where a large number of typhoid patients are treated, it will usually be possible to arrive at a definite opinion within 12 hours, about which time, as statistics show, operation can be undertaken with the greatest prospect of success.

That other conditions may produce symptoms very similar to those of perforation is well known and in at least three recorded cases the operation has been performed under a misapprehension. Mr. Damer Harrisson[15] opened the abdomen in one case and found that the symptoms were due to kinking of the small intestine. Mr. Monier-Williams and Mr. Marmaduke Sheild[16] found perforation of the gall-bladder, and Dr. Herringham and Mr. Bowlby[17] have recorded a case in which nothing more than scybala in the colon was found at the time of operation, the symptoms probably being due to constipation. All these three cases recovered. Gesselewitsch and Wanach[18] refer to an interesting case under Chrostowski's care in which similar symptoms were caused by rupture of two softened splenic infarcts. Some of these conditions and others of similar nature will in all probability account for most of the recorded cases of recovery without operation in supposed perforations of intestinal ulcers.

Details of operation.—The best rule to follow in operating upon these cases appears to be that given by Finney—"Speed and dexterity should be cultivated, but never at the expense of thoroughness." Most writers upon this subject have advocated a median incision below the umbilicus. In my own cases I made a right lateral incision and found that it gave free access to the chief seat of trouble and was convenient in every way. Should it fall to my lot to operate upon any more cases I shall certainly adopt the same procedure. When the abdomen is opened there will probably be escape of gas and more or less feculent fluid. The intestines will be congested and in some cases greatly distended. If lymph be present on the intestinal walls the perforation will probably be in the immediate neighbourhood. In each of my own cases I found the perforation in a loop of the ileum lying in the iliac fossa and passing down towards the pelvis and, except in the first case where the intestines were greatly distended, there was no difficulty whatever in localising it If difficulty be encountered it will be best to find the cæcum and to attempt to trace the ileum from it. During this stage of the operation eventration of the intestine should be avoided as far as possible. If no perforation exist in the ileum an examination of the appendix, the cæcum, and the colon should be made.

The best method of closing the perforation is to turn inwards the edges and to unite the peritoneal coats by interrupted Lembert's or Halstead's mattress sutures. This can usually be done without much interference with the lumen of the bowel. A single row of sutures is sufficient in most cases, for post-mortem records of many unsuccessful cases have shown that there is seldom any subsequent leakage. Frequently it has been demonstrated that a perforation has become sealed even when only a few hours have elapsed between the completion of the operation and the death of the patient. Paring of the edges of the perforation is altogether unnecessary; as Keen says, it is both a waste of time and tissue The same remark applies to excision of the perforated ulcer, a procedure which has been carried out in some cases. In my first case I used a continuous suture of fine silk and I attempted the same in my second case, but owing to the friable condition of the bowel-wall some of the loops cut out. Interrupted sutures are less liable to tear the bowel and are more easily manipulated.

When the wall of the bowel is in bad condition or when there are several perforations near together so that simple suture is insufficient two courses are open—resection of a portion of bowel or the formation of an artificial anus. The former has been carried out in nine cases, three of which were successful (Trojanow, Hill, and Ferraresi). In Mr. Allingham's case[19] the bowel-wall was so rotten that it was brought up to the abdominal wound and stitched there, and Mr. J. E Thompson[20] adopted the same procedure in his second case. As a general rule, considering that cases in which it is not possible to close the opening by sutures will be in a bad general condition, I think that the formation of an artificial anus is a less severe procedure than resection. In seven cases the records state that the perforation was not found at the time of operation. Strange to say, recovery followed in three of these cases (Dandridge, Murphy, and J. B. Deaver).

The interests of the patient will be best consulted by not spending any great length of time in looking for other perforations. Probably a second perforation, if present, will be at no great distance from the first and consequently it is advisable to be content with an examination of the neighbouring portions of bowel. Usually during the operation other ulcers will be seen through the intestinal wall; if these be nearly perforated it is advisable to invaginate them and to suture the serous coat over them.

Finney strongly recommends the cleansing of the peritoneum by wiping with pledgets of gauze. He says that during irrigation there is a very real danger of carrying extravasated material into parts of the abdomen previously uninfected. Most writers, however, recommend free irrigation with salt solution or some mild antiseptic and this would appear to have given the best results. Of the successful cases on record the mode of dealing with the peritoneal cavity is stated in 15. Of these 12 were subjected to irrigation and three to wiping with gauze.

Drainage should in my opinion always be adopted in these cases as it does away with the risk of any re-accumulation in the peritoneal cavity. Of 18 successful cases in which there is information upon this point the wound was completely closed in four (Mikulicz, Wagner, Murphy, and Handford and Anderson). In the remaining 14 cases the wound was either left entirely open or drainage was provided by means of a tube or by strips of gauze.

Results.—The most complete list of cases of this operation hitherto published is that compiled by Dr. Westcott and published by Dr. Keen in his recent work. The table was compiled up to January, 1898, and includes 83 cases in which there is no reasonable doubt as to the diagnosis. Of this number 16 cases recovered. To Keen's list I am able to add three fatal cases published before 1898, but of which I know nothing more than the result, 14 cases which have been recorded subsequently, and my own three cases. The additional cases are as follows. J. H. Nicholas[21]: Two cases reported to the Royal Academy of Medicine in Ireland, 1889; both fatal. Podres and Obalinski, cited by Gesselewitsch and Wanach[22]: One fatal case. Gesselewitsch[23]: One case; operation immediately after the onset of symptoms of general peritonitis; perforation sutured; death after 43 hours. J. B. Deaver[24]: A male, aged 27 years; perforation during the second week; operation within 24 hours; free gas in the abdomen; no attempt made to localise the perforation owing to great distension of intestines; irrigation and drainage; recovery; Widal's reaction obtained. H. C. Deaver (reported by J. B. Deaver)[25]: A male, aged 36 years; perforation in the third week; operation after 36 hours; death. Burrell and Bottomley[26]: Two cases—one recovery and one death. (I have been unable to consult the original reference and therefore know nothing further about these cases.) Handford and Anderson (Nottingham)[27]: A male, aged 27 years; perforation on the thirty-third day of a mild attack; operation after 27½ hours; perforation sutured; peritoneum cleaned by sponges; wound closed without drainage; recovery. Pickering Pick (reported by Rolleston[28]): A male, aged 21 years; typhoid perforation of the appendix; the appendix removed; death on the second day. A case mentioned by Dr. Goodall in the discussion upon Mr. Pick's case at the Clinical Society of London: A girl, aged eight years; perforation during relapse; sutured; death after four days. J. B. Deaver[29]: A female, aged 23 years; perforation on the twenty-first day; operation 15 or 16 hours afterwards; perforation sutured; death after two and a half days. Woodward[30]: A male, aged 18 years; perforation at the end of the second week; operation after nine and a half hours; perforation sutured; the patient recovered from the operation but died nine days later from the typhoid fever; at the necropsy the peritoneum was found uninflamed with the exception of local dry peritonitis around the seat of perforation, Cushing[31]: Three cases. (1) A male, aged nine years; perforation at the end of the second week; sutured; abdomen opened twice subsequently, once for a supposed second perforation and once for kinking of the intestine from adhesions; recovery. (2) A male, aged 18 years,; perforation in the fifth week; sutured; death in four hours. (3) A male, aged 31 years; perforation at the end of the fourth week; sutured; death after eight hours. In a fourth case no perforation was discovered at the time of operation; the patient recovered. Bigger and Campbell[32] (a case reported to the Ulster Medical Society): A male, aged 36 years; perforation during the third week; operation after 10½ hours; perforation closed by Lembert's sutures; death on the fourth day. Altogether we have 103 cases with 21 recoveries. The successful cases on record are as *follows*: Mikulicz (1884), Wagner (1889), Van Hook (1891), Abbe, Netschajew and Trojanow, Dandridge, Ferraresi (1894), Hill, Murphy, Price (two cases), Watson, Sifton (1895), Finney, Brunton and Bowlby (1896), Panton (1897), Deaver, Burrell and Bottomley, Handford and Anderson, and Cushing (1898). In England, including my own cases but excluding the doubtful case mentioned by Greig Smith,[33] 13 operations are now on record. My own case is the third reported in this country in which the result has been successful.

Conditions which influence the results of operation.—The time between perforation and operation is a most important factor in determining the success of the operation. In 69 of the 103 cases we have information upon this point, and by adding the additional cases to the analysis already made by Keen we arrive at the following results:—

ime between perforation and operation.	No. of cases.	Recoveries.	Recovery-rate.
Under 12 hours	17	4	23·5 per cent.
From 12 to 24 hours	26	9	34·6 ,,
,, 24 to 48 ,,	14	1	7·1 ,,
,, 2 to 3 days	6	2	33·3 ,,
,, 3 to 4 ,,	4	0	0·0 ,,
5 days	1	0	0·0 ,,
33 ,,	1	0	0·0 ,,

It is advisable to defer operation until the primary shock which usually accompanies perforation and which as a rule lasts for a few hours has somewhat passed off. The best results have been obtained in cases operated on after an interval of from 12 to 24 hours, although no surgeon would think of waiting for 12 hours provided that other circumstances were favourable. Statistics show that in cases operated upon within 24 hours the recovery-rate has been about 30 per cent., but at the same time we should remember that in all probability some unsuccessful cases have not been reported. After the elapse of 24 hours the chances of a favourable result are very small. Also when marked symptoms of collapse have existed at the time of operation the results have been proportionately bad.

The character of the primary attack of typhoid fever influences greatly the prognosis in these cases, the chances of success being much greater when perforation occurs during the course of a mild attack than when the fever is of a severe type. I find that of the successful cases the disease was reported to be of mild character in five, whilst in two only was it distinctly stated to be of a severe nature. Although I do not think it advisable to limit the operation to perforation occurring in the course of mild or moderately severe cases, yet we must recognise that up to the present time there has been but a small amount of success when perforation has occurred during the height of a severe attack.

An analysis of the cases shows that on the whole the chances of success are rather greater when perforation occurs at a late stage of the disease. We have information upon this point in 76 cases.

	Number of cases.	Number of recoveries.
Perforation in course of 1st week	3	2
,, ,, 2nd ,,	16	3
,, ,, 3rd ,,	33	6
,, ,, 4th ,,	5	1
,, ,, 5th ,,	5	1
,, ,, 6th ,,	1	1
,, ,, 7th ,,	2	1
,, during convalescence	3	2
,, ,, relapse	6	1
,, ,, convalescence from relapse	2	1

From this analysis it would appear that there is some hope of a successful result at all stages of the fever and that it is not advisable to limit the operative procedure to any one stage. The amount of vitality which has been exhibited by some of the successful cases is astonishing. Thus one of Finney's cases, subsequently to the operation, had two relapses of the fever—one of great severity—suppurative middle-ear disease, pleurisy, femoral thrombosis, and neuritis of both legs, and yet made a good recovery. Cushing's successful case underwent another operation for a supposed second perforation and a third operation for intestinal obstruction, all within a fortnight. My own case came safely through a relapse of three weeks' duration.

Operation for typhoid perforation of the intestine has already given a gratifying amount of success. If undertaken within 24 hours of the giving way of the bowel we may confidently expect a recovery-rate of from 25 to 30 per cent., and when we consider that without operation the condition is almost inevitably fatal there can no longer be any doubt as to the advisability of the procedure.

Manchester.

CASES OF HÆMORRHAGE CAUSING GREAT DISTENSION OF THE MALE URINARY BLADDER.

By REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL.

SOME instances of this kind that happen to have recently come together offer material for remark relative to the prompt and direct action which the bleeding usually requires. Cases of great distension of the bladder from this cause, independently of those incidental to malignant growths, are not very common and generally occur in bladders which are muscularly weakened either as the result of a chronic stricture or of an obstructing prostate. The forcing downwards exercised by the normal viscus is the great safeguard against retrograde hæmorrhage following certain operations upon these parts. I cannot remember seeing a severe case of bleeding after an internal urethrotomy for stricture, for instance, where the patient was in possession of the full power of voluntarily emptying his bladder completely. When atonied or weakened the latter is liable to yield under the pressure of bleeding proceeding from a lesion in front of it and then serious and exquisitely painful symptoms may be the result. In some instances the distension thus produced will assume the size of the gravid uterus at about the seventh month. The difficulty in dealing with such a condition is added to by the fact that in the instances referred to the urethra is more or less obstructed. The following cases which are briefly narrated seem to present some points of interest.

CASE 1.—The patient was a man, aged 37 years, the subject of chronic stricture in the deep urethra, for which an internal urethrotomy was performed three years previously and from which he derived so much benefit that he afterwards neglected to use a bougie regularly. Then the stricture began to re-contract and eventually it was found impossible to pass even the smallest instrument. On June 21st,

1898, an attempt was made to dilate under an anæsthetic and some progress was made, bougies up to No. 4 entering without much difficulty or bleeding. I saw the patient on the following day and found that he had passed only a small amount of blood-stained urine since and that his bladder was largely distended, reaching to a level with the umbilicus. He was in great pain and was sweating profusely. He was again placed under an anæsthetic and a small catheter was passed but very little urine escaped. As it was obvious that clotted blood formed the main contents of the bladder and that it must be removed without delay the process of stricture dilatation was at once further proceeded with until a full-sized Lister's bougie could be passed. A large catheter-evacuator was then substituted and a mass of clotted blood was withdrawn by the aspirator as used for litholapaxy. In this way the bladder was soon cleared. A full-sized rubber catheter was then tied in and the patient speedily recovered. Though the full calibre of the urethra is restored the partially atonic condition of the bladder continues, as there is a constant residuum of six ounces or so unless the catheter is used—the result of a neglected stricture though in a young man. It would not have been possible to evacute these clots in any other way except by opening the bladder either in front or from the perineum.

CASE 2.—A man, aged 72 years, with a large prostate for which he used a catheter was seen by me in June, 1898, in consequence of hæmorrhage into the bladder, the latter when seen being enormously distended. Some blood-stained urine had been drawn off, but without lessening the size of the viscus. Several large-eyed catheters were ineffectually tried. As the bladder was evidently full of blood-clots the patient was placed under ether and the evacuating catheter and powerful aspirator were used without avail. As it looked as if it would be necessary to open the bladder I first passed a smooth-bladed lithotrite and broke up the mass of clots just as if it were a stone. In this way a hand-basinful of clots and urine was withdrawn and the bladder was cleared. A rubber catheter was tied in and the patient did well. This was the first time I had used a lithotrite for this purpose, but it answered admirably and made the process extremely easy.

It was suggested that the hæmorrhage had in the first instance been caused by the catheter. I do not believe that this was so. I have seen many cases where old men apparently bled into their bladders instead of into their brains. I refer to instances of vesical apoplexy which are not uncommon. One patient, now aged 75 years, whom I have known for some years, has had his life prolonged, I believe, by this less dangerous substitute for cerebral bleeding. Hence in some of these instances, a "masterly inactivity" is often indicated. When, however, the bleeding attains the proportions stated in this case interference becomes necessary. Failing with the lithotrite there did not appear to be any other alternative than that of opening the bladder above the pubes. The use of the lithotrite, however, proved to be the solution of the difficulty.

CASE 3.—A man, aged 47 years, came under notice at the hospital in November, 1898. For some weeks he had been attending as an out-patient for the purpose of having a No. 6 bougie passed for a contractile stricture in the deep urethra. On the day in question a No. 7 flexible bougie was passed. There was some tightness and a little bleeding followed. The patient returned at night with almost complete retention and with the bladder greatly distended, apparently with urine but, as it proved, more with blood and clots. The house surgeon succeeded in emptying it with an evacuating catheter and aspirator. On the following day the amount of distension and pain was as much as before. As the bleeding was unchecked and as it evidently proceeded from the strictured portion of the deep urethra I had the patient placed under ether again. I passed a medium-sized grooved staff and performed a perineal section, dividing the stricture in the median line. A large gum-elastic rigid drainage-tube was then passed into the bladder. About two pints of clots, blood, and urine were evacuated and the bladder was washed out and the tube was fastened in. For this purpose I use incompressible tubes[1] which were made for me some years ago by Mr J. W. Wood of Liverpool. Being rigid, in case of bleeding from the deeper portion of the section it enables the surgeon to pack round the tube with gauze without interfering with the constant flow of urine from the bladder. This was not necessary in this instance as I took pains to make the section through the deep parts fit the selected drainage-pipe. The tube was removed in seven days and the patient was able to leave the hospital in three weeks with the wound soundly healed. His stricture has been greatly benefited and he now has a full-sized bougie passed when he applies as an out-patient. Here the single proceeding that was adopted at once stopped the bleeding at the spot from which it came, allowed the bladder to be emptied of a mass of clots which could not otherwise have been readily disposed of, and considerably improved the condition of the stricture. Digital exploration of the bladder, as Sir Henry Thompson described it, has reduced to simplicity the old perineal section without restricting its application.

I may here incidentally refer to a somewhat curious case of prostatic hæmorrhage and vesical distension recently seen. It was the case of a patient with prostatic enlargement who was entirely dependent upon the catheter. Whilst travelling to the North by an express train he had occasion to use his flexible catheter in the lavatory department attached to his carriage. Just as he had inserted the instrument and as the train was passing over some points he was thrown with great violence against the side of the carriage before he had time to withdraw the catheter. He felt hurt and faint and considerable hæmorrhage by the urethra followed and continued with much distension. I was requested to go down to see him with his medical attendant a few days afterwards and I found that he had suffered most seriously from the injury. The distension had been relieved by the catheter but the wound of the prostate, from which no doubt the hæmorrhage came, was followed by a sharp attack of epididymitis; the patient, however, made a good recovery. From the examination of the circumstances connected with the injury it was a marvel that the patient escaped a ruptured bladder. The case is not without its practical aspect.

Lower Berkeley-street, W.

THE OCULAR PHENOMENA ASSOCIATED WITH CHEYNE-STOKES RESPIRATION.[1]

BY ARTHUR L. WHITEHEAD, M.B., B.S. LOND.

THE ocular phenomena which occur in association with Cheyne-Stokes breathing are worthy of attention not only as clinical facts, but as possibly helping to throw light upon the etiology of this interesting symptom. Cheyne-Stokes breathing as described in the words of Stokes[2] consists in the occurrence of a series of inspirations increasing to a maximum and then declining in force and length, each inspiration being less deep than the preceding one until they are all but imperceptible and then a state of apparent apnœa occurs. This is at last broken by the faintest possible inspiration, followed by one more decided, marking the commencement of a new ascending and then descending series of respirations. In some cases the sequence of events is not so perfectly regular.

In the majority of recorded cases of this periodic alteration of the rhythm of respiration no eye symptoms whatever have been observed, but in a certain number definite disturbances of the intra- and extra-ocular muscles have been seen. The first recorded observation was made in 1866 by Leyden[3] who in the course of some experimental observations upon the brains of animals succeeded in producing Cheyne-Stokes breathing and noted that the pupils were contracted and that a form of nystagmus set in during the pause in the respiration Leube[4] reported four years later a case from Ziemssen's clinic of mitral stenosis with ascites in which Cheyne-Stokes breathing came on after a dose of morphine. He observed that the eyes were open during the stage of breathing and were closed during the cessation of respiration, and that during the pause the pupils were contracted and failed to react to alterations of light; with the first returning breath, or in some cases shortly before it, they dilated again. Synchronously with the contraction of the pupils there was an automatic conjugate deviation of the eyeballs, the right eye turning out and a little downwards and the left inwards and a little down to a corresponding extent, this movement being repeated each time during the pauses, the eyeballs returning to the normal position during the respiratory period. Hahndel,[5] Merkel,[6] Carrer,[7] Sacchi,[8] Biot,[9] and several others have described similar cases with pupils contracted and not reacting to light during the pause, accompanied at times by conjugate deviation of the eyeballs. Cuffer[10] has produced typical Cheyne-Stokes breathing with the pupil changes described above by the injection of ammonium carbonate into a vein; and Smirnow[11] reports similar phenomena together with anæsthesia of the cornea occurring in animals after breathing sulphuretted hydrogen mixed with air. Hein[12] mentions a case in which the pupils were of moderate size during respiration and became gradually smaller with the descending phase and gradually widened with the ascending series of respirations. Robertson[13] describes two cases of cerebral hæmorrhage with similar pupil changes, in one case the pupils continuing to react to light but not doing so in the other one. Finlayson[14] was the first to report a case of Cheyne-Stokes breathing in which there was a rhythmic enlargement of the pupil with each individual respiration followed by a contraction of less degree with each expiration during the ascending phase and a reversal of the process during the descending phase, so that the pupil was contracted during the pause and widely dilated at the period of deepest breathing. Terrien[15] relates a case in which the pupils contracted down to the size of a needle-point during the stage of apnœa and became so dilated with the maximum inspiration as to render the iris almost invisible. At the same time there was a periodic anæsthesia of the cornea but not the slightest movement of the eyeballs. Langer[16] describes a case in which there was a periodic convergent strabismus with contracted but unequal pupils during the pause. It is interesting that no changes in the retinal vessels have been observed in association with these pupil changes; Schepelern,[17] Ewald,[18] and Knies[19] have specially investigated this point and reported in the negative. Dr. Barrs has given me the notes of a very interesting case of a child presenting many of the symptoms of tuberculous meningitis. On the fourteenth day of the disease Cheyne-Stokes breathing set in with associated movements of the eyes and head. The sequence of events was as follows: "The child sighs and half groans as if a pain has seized her in the head and then the ascending phase of breathing and head-rolling begins, the head being carried with each inspiration to the left with greater and greater excursions till the maximum is reached and gradually subsides again." With the movements of the head were associated conjugate movements of the eyeballs. It is interesting to know that this child recovered in the course of a few days and that she has remained perfectly well ever since.

[4] Berliner Klinische Wochenschrift, 1870, p. 177.

We now have to consider some rather anomalous cases which present many of the symptoms above described but without Cheyne-Stokes breathing being present. Bullard and Wentworth[20] have reported the case of a child, two years old, who was suffering from whooping-cough and convulsions in which slight twitchings of the face set in and finally horizontal nystagmus with Cheyne-Stokes rhythm manifested itself. The pupils remained equal and reacted to light. Ultimately coma set in and death followed. No post-mortem examination was obtainable. The nystagmus was horizontal and began with rapid movements, the oscillations becoming progressively larger and more extended to a certain point and then diminishing in the same manner. A pause then ensued which was followed by a repetition of the previous rhythmical movements. The condition recurred at intervals during the day. There was no Cheyne-Stokes breathing and there were no marked pupillary symptoms. Dr. J. A. Gibson[21] has related the case of a child who presented all the symptoms of subacute tuberculous meningitis, but he remarks that owing to the ultimate recovery of the patient this may possibly appear to have been an error in diagnosis. He says, "During the course of the disease when watching her carefully one day a periodic closure of the eyelids attracted my attention and on further observation it was easy to determine that along with the closure of the lids there was a simultaneous contraction of the pupils and a state of complete unconsciousness. This condition remained for several seconds, the eyelids were then raised, the pupils dilated, consciousness returned, and the child raised her head to look about. The conscious state was present for a short time and was in its turn followed by the unconscious condition. In this case there was never, so far as my observation went, any tendency to a periodic change in the rhythm of the breathing." Belonging to this group of cases, each member of which is obviously allied to the others, differing only in detail and filling a gap in the series, are two cases observed by myself.

CASE 1.—A man, aged 23 years, was the subject of chronic left otorrhœa. He suffered from headache and general malaise, and pyrexia had been present for 10 days and was followed by tenderness of the mastoid. Opening and draining the mastoid cells did not relieve the symptoms, and drowsiness followed by stupor set in. The pulse was 100 and regular; the temperature was between 102° and 104° F., and the respirations were about 32 to the minute and perfectly regular. There was some rigidity of the limbs with exaggerated knee-jerks. At this stage I noticed that the pupils although equal and reacting to light were undergoing periodic rhythmic fluctuations in size. At the commencement of the cycle the pupil was about 1·5 millimetres in diameter and gradually and steadily dilated up to about five millimetres, subsequently slowly contracting to its former size, the whole stage occupying about 50 seconds, and after remaining contracted for a few seconds the cycle was repeated. At no period was the reaction to light interfered with and there was no nystagmus or other deviation of the eyeballs, and as mentioned above no alteration in the rhythm of respiration. Subsequently coma set in and was followed by death. At the necropsy a patch of localised meningitis was found over the affected temporal bone, with some flakes of lymph dotted about over the general surface of the pia mater.

CASE 2.—A man, aged 32 years, suffered from acute left otorrhœa of five days' duration. Headache, pyrexia, slight rigors, and some drowsiness were the leading symptoms. The mastoid antrum was opened, but no collection of pus was found and the lateral sinus which was also explored was found to be healthy. The pyrexia continued and there was considerable drowsiness alternating with periods of restlessness, but consciousness was not at all impaired and responses to questions were ready and intelligent. The knee-jerks were brisk and equal. The temperature was 101°, and the pulse was 100, full, and regular. The respirations were 24 to the minute and perfectly regular. At this stage the pupils displayed the same periodic movements which have been described in connexion with the first case. Ultimately coma set in, followed by death. At the necropsy a subdural abscess was found which had burst through the dura mater and had involved the right lobe of the cerebellum.

Considering all these cases, reported by so many observers, it is evident that the ocular symptoms met with in association with Cheyne-Stokes breathing are of considerable variety, and, moreover, that they may be observed in what we may conveniently call a Cheyne-Stokes state or condition apart from any disturbance in the rhythm of respiration. Every variety of case may be seen, from simple Cheyne-Stokes breathing to the complete clinical picture of persistent and regular Cheyne-Stokes respiration accompanied during the pause by unconsciousness, closed eyelids, contracted pupils, and lateral conjugate deviation of the eyeballs, the pulse during this period being frequent, small, and of moderately high tension. At the end of some seconds consciousness returns, the eyes open, the pupils slightly dilate, the pulse loses some of its tension, and a superficial respiration follows. Cases intermediate in character with one or more of these phenomena associated with the Cheyne-Stokes breathing are recorded, clearly showing that whatever may be the nature of the condition underlying this group of symptoms occurring in the Cheyne-Stokes state, it may produce the effects which depend upon it by affecting the lower centres in the first place and spreading upwards to the higher, or by acting upon the higher first and afterwards invading the lower centres. Further, the cases reported by Ballard and Wentworth, by Gibson, and by myself, show that the periodic changes produced by alterations in the centres may commence in, and be limited to, those which are not concerned in vital phenomena.

It is not desirable to consider in detail the numerous theories which have been suggested at various times to explain the causation of Cheyne-Stokes breathing. These have been fully stated and adequately discussed in Gibson's exhaustive monograph on the subject. It is quite clear, however, that any theory to be accepted must satisfactorily account for the whole of the associated phenomena. Filehne's[22] well-known theory, to which many writers still adhere, that the action of the vaso-motor centre is an important or predominant factor, is obviously entirely inadequate to account for phenomena which may occur without any changes in the pulse or even in respiration. A modification of the theory originated by Luciani[23] and elaborated by Rosenbach[24] and by Gibson,[25] that some special condition of the respiratory and other centres is responsible for the whole series of phenomena, is the only explanation at all satisfactory. The investigations of Langendorff[26] on kittens and of Sherrington[27] and others on frogs show that the respiratory centre is automatic and when freed from the influence of the higher centres becomes periodic in action. This is confirmed by the observation of Mosso[28] and others that periodic breathing is common in hibernating animals, and has been not infrequently observed in the human subject during deep sleep, especially after great exertion. Other medullary nuclear centres governing the heart's action and blood-pressure exhibit the same periodic tendency when cut off from the influence of the higher centres. If by cerebral pressure, by uræmic blood, by deficient arterial supply, or by the administration of certain drugs the control of the higher centres is lessened or abolished, the lower centres will tend to show periodic variations in the manifestation of their activity, more or less regular inversely as the control is exercised. This is the condition which I have ventured to describe as the Cheyne-Stokes state. The anatomical relations between the various nuclear centres affected in the production of this state are obvious and that anyone or several or all may be involved is equally clear, but the cause of the selective action is as yet quite unknown. It will only be by the careful comparison of accurate records of cases of a nature allied with those now reported that we can hope to arrive at a satisfactory solution of this problem and at the same time determine the diagnostic or prognostic value of the individual phenomena of this group of symptoms.

Leeds.

"COLLES'S LAW" OR "WALLACE'S LAW"?

BY JOHN A. SHAW-MACKENZIE, M.D. LOND.

THE association of the name of Colles with the clinical observation "that the child born of a mother who is without any obvious venereal symptoms . .... will infect the most healthy nurse whether she suckle it or merely handle and dress it . . yet that this child is never known to infect its mother even though she suckle it while it has venereal ulcers on the lips and tongue," seems to be generally accepted in this country. Subsequent confirmation of such observations by Diday led him in conformity with the law of oneness of constitutional syphilis to refer to Colles's constant rule as "Colles's law," and, notwithstanding his admission in acknowledgment of the view of Baumes and a possible case of Cazenave that "this rule like every other must have its exceptions," he nevertheless thinks that "we are fully justified in asserting that a child born syphilitic through the agency of its parents never communicates the disease to the mother who suckles it." The validity and interpretation of Colles's law have comparatively recently been contested by Dr. Coutts[1] and Dr. G. Ogilvie,[2] and while the probability of exceptional cases has since become generally recognised their interpretation, and consequent deductions are controversial points. On the one hand, Mr. Hutchinson, relying upon the general rule as opposed to the constant rule that one attack of syphilis confers for the most part protection against subsequent infection, regards these rare exceptions (a case of which he has never met with himself) as second affections, analogous to the cases of second affections in the male.[3] On the other hand, Dr. Coutts has suggested that the mother's apparent immunity may be due to the antitoxins of her infant in utero and that such immunity is not equivalent to acquisition of the disease itself. These exceptions may therefore be regarded as primary acquisition of disease. I myself, relying largely upon the repetition of manifestations in subsequent conceptions and during the puerperal period, have ventured to suggest that the mother's immunity, in accordance with Mr. Hutchinson's views, is equivalent to acquisition of disease, and that these exceptions might possibly be regarded as relapsing disease or, as noted in a case of Whitehead's, true secondary sore of the nipple with enlarged axillary glands induced by suckling. On the other hand, relying upon the disappearance of symptoms after delivery, I have ventured to suggest that the freedom from symptoms and immunity were conferred on the mother by processes in herself connected with full pregnancy, involution, and lactation, and that therefore these exceptions might be regarded as re infections.[4]

In turning over the pages of THE LANCET of March 25th, 1837, recently, I unexpectedly came across a review of Colles's work and much to my surprise I found that considerable doubt was thrown upon the priority of Colles's observations in general. Appeal is made to the original work of W. Wallace, whose oral lectures in Dublin had appeared and were appearing in THE LANCET for 1833–34 and 1836–37. On referring to these lectures all the observations of Colles appear, apparently independently. Some of these observations—viz., the acquisition of disease by the "dry" nurse; in "wet" nursing; the transmission from secondary disease and the consequent modification—appeared in THE LANCET of Feb. 13th, 1836; others—viz., the contagious nature of the two forms of disease (hereditary and acquired) in the infant; the acquisition of disease from a strange child "not her own child"; disease as well as apparent immunity in the mother of a diseased infant—appeared in THE LANCET of May 7th, 1836, which was undoubtedly before the publication of Colles's work which was dated Jan. 20th, 1837, while the lecture dealing especially with the general immunity of the suckling mother to the disease of her own child appears in THE LANCET of May 20th, 1837. Another observer of similar facts appears in THE LANCET of March 11th, 1837. The remarks of Dr P. Doepp, physician-in-chief to the Children's Hospital, St. Petersburg, on certain diseases in children, founded on a total number of 18,000 patients presenting themselves at that hospital from 1830 to 1833, are published from the translation of Dr. P. H. Green. Dr. Doepp testified to the hereditary (paternal) origin of disease in the infant as opposed to disease acquired from the mother during delivery; to the disappearance of manifestations in the case of a mother during pregnancy; to the immunity of the suckling mother to disease of her own child; to the fatality attending the separation of such infants from the breast; and to the devotion of those who suckled them in spite of the attendant risk.

The question of priority, however, is of minor importance in comparison with the observations and interpretations of Wallace as contained in these lectures published in THE LANCET and "through the medium of this journal" announced to "the whole profession"—"productions which for richness in fact, exactness of detail, and scientific precision of arrangement, have never been surpassed, probably not equalled by any series of clinical discourses hitherto delivered in these kingdoms." "You remember the child," wrote Wallace on May 20th, 1837, "which you saw in the dispensary labouring under symptoms of syphilis. I mean the child which had the peculiar cry, the scaly lips, and the excoriated mouth, the bleared eyes, and the general eruption of reddish brown stains. You also remember that I pointed out to you that the mother who nursed this child was free in appearance from all kind of disease. Her nipple had not suffered although the child's mouth was so much affected. Now you know that such children are most apt to communicate disease to such sound women as nurse them. Why, then, did not this child communicate disease to its mother who nursed it and who seemed to be sound? I reply, because the mother was insensible to the action of the poison in consequence of her constitution being already contaminated. You may say she was sound: I admit she was so to external appearance, but you have, in my opinion, a proof in her having given birth to an unsound child that she was unsound. In fact, the mother of a child congenitally syphilitic is not susceptible of having disease produced in her by suckling her own child—at least so long as she remains in the same state as she was in when she gave it birth. I have never seen a mother injured by her own disordered child. This is a reason among many others that such infants should be nursed by their mothers. But if a mother be separated for a time from a child and cured and if the uncured child be brought into contact with her there is reason to believe that she would receive the infection. I have seen cases which prove this." In explanation and support of these views he brings forward the results of inoculation experiments on a man whom he calls "P. D" and on his wife whom he calls "M. D." to whom the man had given obvious disease. The man was unsusceptible to auto-inoculation and the woman was unsusceptible to auto-inoculation. She was, however, susceptible to inoculation from the man from whom she had originally acquired the disease. "What, then," he asks, "was the cause that inoculation was not followed in P. D. by any effect? By his case and by many others of a similar kind I have been led to the discovery of an important law relating to the propagation of the venereal poison. It is this: as soon as the constitution of any individual becomes contaminated with this poison all parts of his body are rendered insensible to inoculation with the matter of his own sores or of analogous sores of another individual although such matter has the power of producing disease in a sound person." With regard to the woman he writes, "We are authorised from this experiment to infer that M. D. was susceptible of the influence of the poison of P. D. although insensible to her own poison, which had emanated originally from that of P. D. You must observe that this conclusion corresponds with the general conclusion already made—viz., that a system labouring under a venereal disease is capable of being contaminated by a less exhausted virus than its own. Now, although M. D. originally received this infection from P. D., as soon as her disease became constitutional its virus was exhausted one grade more than that of P.D. and consequently she was still susceptible of the influence of the poison of P. D., although insensible to her own." A case which he adduces as an analogy to the reinfection of a mother by her own child is remarkable and suggestive. It is that of a man who obviously infected his wife. Separated from her and undergoing proper treatment his symptoms subsided, but on resuming cohabitation he acquired fresh disease of a primary exanthematic character, followed in turn by constitutional symptoms. Diday noted the manifestations reappearing in the mother in subsequent conceptions. He regarded them as fresh aggravations of poison from the fœtus in utero. His apparent forgetfulness of "Colles's law," to which he had given his adhesion, led me to suggest relapse rather than fresh infection under the stimulus of conception, in similar cases, as well as in these local sores, often seen in men who have previously suffered and who may or may not have exposed themselves afresh to admitted sources of contagion.

Not only does Wallace's work throw light upon the nature of immunity in the mother, from inoculation experiments, but also upon that of reinfection in exceptional and similar cases. Moreover, light is thrown upon many other questions which at the present day are the subject of anxious inquiry and controversy. It is a little remarkable that Wallace's work should have remained "latent" for so long. This has arisen probably from the fact of his death in 1838 preventing the publication of a second *volume* on constitutional disease which he tells us in the preface of his first published volume (1838) dealing with "*primary*" disease and its varieties would follow.[5]

Grosvenor-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON THE RADICAL CURE OF HYDROCELE BY PERINEAL EXCISION OF THE GREATER PART OF THE SAC.

By H. MILTON, M.R.C.S. ENG.

HYDROCELE is one of the most frequent conditions with which the surgeon in Egypt has to deal and its treatment by puncture and injection of iodine is of old standing in that country. In quite recent times this treatment was largely carried out by barbers and I know a native *hakeema* (or lady doctor) of high standing who has a well-merited reputation as regards this particular operation. In my experience, however, the results given by any form of injection are very uncertain and I have long abandoned this method entirely and have treated all my cases by incision. In my earlier operations I incised directly through the scrotal tissues on to the hydrocele and I found very great difficulty in avoiding suppuration. This danger of infection is chiefly due to the nature of the integument and to the difficulty of applying a satisfactory dressing. Later I adopted the method recommended by Kocher of dislocating the hydrocele into the abdominal wall and incising over the inguinal canal. The results thereby obtained were more satisfactory but I frequently met with hæmorrhage into the scrotum subsequently to the closure of the wound. This risk of hæmorrhage is due, in part at all events, to the pressure on to the cord produced by the pad placed over the incision and owing to the laxness of the scrotal tissue this hæmorrhage may go on unperceived until a rise of temperature and pain necessitate a change of dressing and disclose a scrotum as large and as black as a hat. I have in all my recent operations adopted a method which by providing perfect drainage obviates the danger of hæmatoma and which has given me a series of most excellent results with an entire absence of complications. This method, while adopting the principle of dislocation, changes the position of the incision from the inguinal region to the perineum.

The operation is very simple. A purge and enema having acted satisfactorily the patient is placed in the lithotomy position, the perineal and adjacent regions are shaved and well scrubbed with soap-and-water and rubbed down with alcohol and sublimate, and the neighbouring parts are protected with sterile cloths. An assistant seizes the scrotum and causes the hydrocele to project into the perineum, forcing it down as far as it will go. An incision is then made in the perineal skin over the lower part of the projection from some two to three inches in length. A few strokes of the knife expose the tunica vaginalis and an incision into it allows its contents to escape. As the sac contracts its walls are seized with artery forceps and are gradually delivered through the incision. The hydrocele is then split from one end to the other and the larger portion of its walls is removed with scissors, the portion over the testicle and within half an inch of it being left untouched. The removal of this portion of the hydrocele is quite useless and more than that is harmful inasmuch as it leads to oozing and is nearly always followed by orchitis. All bleeding points are clamped and tied and the testicle is returned into the scrotum. A small drain is introduced and the skin incision closed with a fine suture. A perineal pad is applied and over this a large dressing which covers the scrotum and the penis, and by means of a T bandage or a sling from the neck holds them well up on the penis. The outside dressing is removed for urination and the perineal pad is changed daily as it tends to get soaked with perspiration. On the second day the tube is removed, on the fifth day the stitches are removed, and on the following day the patient can get up and if necessary go about his business but wearing a suspender and a perineal pad.

---

[5] Samuel Lane refers, however, to his work and untimely death "Lectures on Syphilis," THE LANCET, June 18th, 1842.

Four points require attention. 1. Care must be taken not to incise the testicle instead of the hydrocele sac. Usually inspection and palpation leave no doubt on the matter, but if for any reason, such as a thickened sac, the decision is difficult the passage of a hypodermic needle will settle the question without appreciable injury to the testicle. 2. Care must be taken to avoid any injury to the cord or testicle and the most delicate handling only must be practised. 3. All drainage must be arrested and a drain must be left for the escape of any oozing. This latter precaution is, I think, of great importance to prevent hæmatoma of the scrotum and the presence of a tube and its withdrawal on the second day offers no considerable inconvenience. 4. The scrotum must be kept well up on the pubes during convalescence.

Cairo.

NOTE ON A RAPIDLY-GROWING OVARIAN TUMOUR COMPLICATING PREGNANCY; OVARIOTOMY; MISCARRIAGE; RECOVERY.

By DANIEL MOWAT, M.D. EDIN.

THE following case of an ovarian cyst growing rapidly during pregnancy and its removal verifies the remarks made by Dr. W. Duncan in THE LANCET of Feb. 4th, but in this case the patient unfortunately miscarried about two hours after the removal of the cyst, most probably from the too free handling of the uterus.

A woman, aged thirty-one years, who had had two children and one miscarriage, had suffered severely from metrorrhagia for several years. On examination in January, 1890, I found the uterus enlarged and fibroid nodules on the posterior wall. The ovaries were normal in size In January, 1892, she consulted me and stated that she was about three months pregnant but that she was very large. On examination I found the abdomen much larger on the right side than on the left and dull on percussion. Per vaginam the uterus was enlarged to the fifth month and was pushed to the left side. A cystic swelling somewhat larger than a cocoanut was felt towards the right of the uterus. This swelling was diagnosed to be an ovarian cyst and the patient was strongly advised to go to a hospital for operation as she only had three rooms in a small house and was unable to obtain skilled nursing. This, however, she steadfastly refused to do and she was therefore kept under observation, but the swelling increased so rapidly in size that she was soon unable to leave her bed. As her condition was now serious I asked Dr. Duncan of Stamford-hill to see her. This he kindly did and he confirmed my previous diagnosis and expressed the opinion that an operation must be performed at once. To relieve the immediate distress I tapped the cyst, but owing to the gelatinous nature of its contents nothing came through the cannula

On March 31st Mr. Reynolds of Highgate kindly gave the anæsthetic and Dr. Duncan of Stamford Hill assisted me in the operation. The usual incision in the central line was made and the bleeding vessels were seized at once. The great distension had caused thinning of the integuments and the cyst wall had ruptured at the point where it had previously been tapped. Adhesions had also taken place round this point spreading on the right side into the iliac fossa. These were separated and the tumour was emptied of its gelatinous contents which had to be scooped out with the hand The tumour which was of the right ovary was then withdrawn, several omental adhesions were separated, and the pedicle was tied in the usual manner and dropped into the abdominal cavity. The pregnant uterus now gradually resumed the normal position in the centre of the abdomen where it immediately began to contract. The peritoneal cavity having been repeatedly washed with warm boric lotion the edges of the incision were brought together with silkworm gut. Two hours after the operation I found the patient in labour and she was shortly delivered of a fœtus six months old. The after pains were very severe but were relieved with morphia The stitches were removed on the seventh day. A slight attack of phlegmasia alba dolens developed on the seventeenth day which prevented the patient getting about as quickly as she otherwise would have done. The result is very satisfactory, more especially as the operation had been considerably delayed by the patient's refusal to enter a hospital. It was, indeed, only undertaken to save her from impending death. The operation was performed in a small room in a poor locality and the only nursing she had was from her neighbours. Since the operation the patient again became pregnant, but unfortunately miscarried at the fifth month

Stamford Hill, N.

NOTE ON A CASE OF BRADYCARDIA.

By CHARLES ORMEROD, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

A MAN, aged 83 years, well-nourished and extremely phlegmatic in disposition, complained of feeling very cold and of having occasionally what he called a "fit." At these times he turned white and felt faint. The attack was evidently cardiac in character. These attacks occurred on any attempt to get out of bed. The family history of the patient was unimportant. He had had two attacks of rheumatic fever, the second when he was a young man. He had been a non-smoker and had always been very abstemious in his habits. No drugs had any effect on the rate of the heart. On examination the heart dulness was found to extend upwards to the third costal cartilage. Its lateral limits were not markedly increased, the apex beat being in the fifth interspace just inside the nipple. There was a systolic murmur at the apex, inaudible at the back. The heart sounds at the base were natural, but all the sounds were very faint and distant. The pulse was extremely slow. On one occasion only 26 beats and on another 29 beats per minute were counted, but throughout the year during which he has been under my observation the pulse has ranged from 30 to 36 beats per minute. The liver dulness has not obviously increased. There is no albuminuria and no epigastric pulsation. Probably the cause of the extremely slow pulse in this case is some degeneration of the cardiac muscle which is possibly fatty in nature.

Liphook

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ROYAL FREE HOSPITAL.

A CASE OF SARCOMA OF THE CORPORA CAVERNOSA; REMOVAL; REMARKS.

(*Under the care of Mr.* W. H. BATTLE.)

IN two points the following case is remarkable. In the first place the disease is one of extreme rarity, very few cases indeed being recorded, and in the second place the long duration of the case is noteworthy, for more than seven and a half years intervened between the first appearance of the disease and the death of the patient. Another point of interest is the enlargement of the breasts; it is said to occur in cases of malignant disease of the lungs.

The patient, a very tall man, aged 50 years, was first seen in November, 1892 Two years and six months previously he had noticed a difficulty in micturition and six months later a very small swelling appeared in the middle of the perineum. As it gave rise to no pain or inconvenience he took no further notice of it. It increased in size and caused a sensation of weight and also some slight pain on walking. The patient was advised to go into the hospital but he declined; however, in January, 1893, he consented to become an in-patient

There was nothing noteworthy in his family history beyond the fact that his mother and one sister had died from consumption. His general health was very good and his thoracic and abdominal organs appeared to be healthy but the arteries generally were a little thickened. In the centre of the anterior part of the perineum was a fixed rounded prominence, resistant on palpation and of the size of a duck's egg; no fluctuation could be obtained and it was thought to be a new growth or possibly a chronic abscess. On Jan. 30th, 1893, the following operation was performed. The patient was anæsthetised, placed in the lithotomy position, and a No. 11 catheter was passed. The perineum having been shaved and cleansed an incision was made in the mid-line of the perineum, reaching from a point half an inch in front of the anus over the middle of the swelling to the scrotum. This incision was deepened until the tumour was reached; it proved to be very vascular and when it was dissected away from its surroundings it was found that it had arisen in connexion with the left corpus cavernosum, but extended across at the junction of the two into part of the right corpus cavernosum. The left corpus cavernosum was removed from its posterior attachments to the bone, the right one was cut across well behind the part invaded by the growth, and the tumour removed after section of the two corpora which were joined under the scrotum. No opening was seen in the urethra, but it was somewhat difficult to separate it in front, whilst it is probable that the necessary traction during the removal of the tumour had bruised it. The oozing of blood which was severe was stopped by means of Paquelin's cautery. The wound was swabbed out with a solution of chloride of zinc (40 grains to the ounce) and was stuffed with gauze soaked in glycerine and iodoform. The skin incision was partly closed with carbolised silk sutures and a sal-alembroth dressing was applied. The catheter was retained in the urethra. After the operation the temperature became variable, rising to 102°F., and on Feb. 5th to 103°, but it fell to normal on the 8th. The wound was dressed daily and on Feb. 5th as the stitches were tense, they were removed, and after that a little urine escaped by the wound. The quantity of urine thus escaping increased until nearly the whole of the urine passed by this channel. Occasional incontinence of fæces occurred from the 14th and he complained much of pain "in his bowels," but no cause for this pain could be found. The wound began to heal and less urine was passed through it, and by the 24th most of the urine passed by the urethra, and on the 25th the catheter was left out. Turpentine stupes appeared to relieve the abdominal pain. On March 8th he was able to get up in the evening; the wound had almost healed and very exceptionally a small quantity of urine still escaped through it. The abdominal pain still occurred occasionally and the involuntary defecation still continued. Both these symptoms, however, improved later. On April 8th he had a discharge "like dirty water" from the rectum; it was thin, brownish coloured, and very offensive, but nothing could be found on examination. About the same time some pain and tenderness were present in the left iliac fossa and a small swelling of about the size of a cherry could be felt there. The pain had much diminished, the involuntary action of the bowels had ceased, and the wound of the perineum having completely healed all urine was passed naturally when he left the hospital on April 15th.

For six months after leaving the hospital he was apparently quite free from the disease; then the growth began to reappear in the old scar. It caused him no inconvenience or pain until in December, 1895, he had an accident, a fall from a scaffold, causing "concussion of the brain," and for this he was for five weeks in the West London Hospital and during his stay there the growth was noticed. It became painful and grew more rapidly. He was readmitted into the Royal Free Hospital on Feb. 19th, 1896. At that time his general condition was hardly changed, though he looked sallow and ill. In the perineum were found some small, rounded swellings along the middle line and also in the scar of the former operation. On examination per rectum the situation of the left crus penis was occupied by a firm ovoid swelling of about the size of a small hen's egg. It was decided to attempt the removal of the growth. The patient was anæsthetised and placed in the lithotomy position and the perineum was cleansed. Mr. Battle then made an incision through the skin and subcutaneous tissue on the left side of the perineum parallel to the ramus of the ischium and a finger's breadth internal to it. The growth was dissected out; it was very vascular and bled freely and the wound had to be packed several times with gauze and sponges to stop the bleeding. The growth extended as far as the pubic ramus and a second incision was made outwards for two inches from the centre of the first incision. The more anterior of the recurrent growths were left untouched at that time as the patient had lost a good deal of blood; the edges of the wound were sutured, no drainage tube being used, and the wound was dressed. The wound was dressed daily; no marked rise of temperature occurred, it never reaching 101°. After a day or two the bowels began to act involuntarily, as after the former operation. The wound healed well and on March 8th the patient left the hospital with the intention of returning shortly for operation for the removal of the remaining nodules of the growth. He did not, however, return to the hospital until August 31st, 1896, and then he said that he had had pain both when sitting and walking for several months and he had not been able to work properly since leaving the hospital. He had no trouble with micturition or defecation. On examination a firm, lobulated mass was found in the anterior part of the perineum. His general condition was not so good as it had been when he was in the hospital previously. He had a troublesome cough and numerous râles were heard all over the chest. As it was considered that these pulmonary signs might be due to secondary growths in the lungs Dr. Andrewes was requested to examine him. On *Sept. 11th Dr. Andrewes found somewhat impaired* resonance about the right apex with signs of a diffuse bronchial catarrh. There were no definite signs of any secondary deposit in the lungs but the signs present were not incompatible with such deposits. Mr. Battle decided not to operate. The violence of the cough increased and on the night of the 22nd the patient brought up with the cough a considerable quantity of bright blood. The hæmoptysis continued in varying amount and though his general health seemed to improve with tonics his cough continued to be very troublesome. Some enlargement of the mammæ occurred, especially on the left side. The physical signs hardly altered. The cough increased in severity and the patient grew weaker and on *Dec. 7th he was removed to* Highgate Infirmary where he died early in 1897. No post-mortem examination was made, but the symptoms were those of new growth in the lungs. On microscopic examination of the portions of growth removed at each operation it was found to be a spindle-celled sarcoma.

Remarks by MR. BATTLE.—Sarcoma of the penis is a rare condition in surgical practice and this case has been considered worthy of publication on account *of the part in* which the growth originated and the somewhat unusual method of removal adopted. It is questionable if any other method of treatment would have afforded equally good results. It is probable that local recurrence would have been met with at a similar interval had the whole penis been removed and the urethra brought out in the perineum, for the recurrence was as marked in the tissues on *both sides of* the perineal urethra as in the posterior extremity of the united corpora cavernosa. The *muscles* of the perineum were adherent to the growth in parts at the first operation and although no tumour was *apparently* left there is no doubt that some infiltration had taken place into them. The course of the urethra could be readily ascertained during the operation, for its position was manifested by the catheter, and this was at no time visible, so that the discharge of urine from the perineum during the after treatment was probably the result of sloughing of a damaged portion. There can be no doubt that the patient was much more comfortable and far happier after this operation than if a more extensive one with removal of the penis had been performed. He had been warned of the probability of recurrence and *had promised to* return if there was any reason for thinking that there was anything amiss. I am indebted to Mr. Durham for having sent him to me for the second operation. On that occasion it was evident that the growths requiring removal were in a vascular region and that it might not be advisable to remove all at once; this was explained to the man who gave permission to me *to act* as I thought best. There was considerable hæmorrhage and a marked general effect on the system from the hæmorrhage which ensued on removal of one growth, so further operation was postponed. He afterwards withdrew his promise and refused operative treatment until it was too late. The hypertrophy of the breasts which was marked and lasted for some six to eight weeks was a curious state for which I can offer no explanation. I have not before met with it in secondary sarcoma of the lungs. Microscopical examination of the growth showed spindle- and round-celled sarcoma, chiefly the former.

SALOP INFIRMARY.

A CASE OF PURPURA HÆMORRHAGICA IN WHICH STREPTOCOCCI WERE FOUND IN THE BLOOD; NECROPSY.

(Under the care of Dr. E. CURETON.)

HÆMORRHAGIC purpura probably arises from several causes, though in all cases it is likely that a toxin is present in the blood. In the following case the staphylococcic infection was in all probability the cause of the purpura, but it need not follow that all cases of this disease are staphylococcic in origin. An important point may be borne in mind, that in every case of purpura a bacteriological examination should be made of the blood; it is only by a regular, systematic investigation of all cases that we shall be enabled to form clear conclusions as to the etiology of this affection. For the notes of the case we are indebted to Dr. G. Gocher, late assistant house surgeon.

A schoolboy, aged 11 years, was admitted into the Salop Infirmary on Oct. 15th, 1898, under the care of Dr. Cureton, for general ill-health and an eruption all over him. For three weeks before his admission into the hospital the mother noticed that he was covered with spots. For the first two weeks he went to school as usual, but during the third week he stayed at home complaining of a sore throat and weakness in his legs. During this time he did not appear to be feverish, but he would not take his food and during the latter part of the third week he began to vomit. The mother then, seeing that he was really ill, took him to a medical man who advised that the patient should be taken to the hospital. The medical man kindly supplied the following information: "I found petechiæ on the body and limbs and the boy looking ill and weak. Four days later I saw him again and he seemed worse for there was bleeding from the mouth and right ear. The boy lived in a wretched home, was badly clothed, and was fed mainly on bread and jam." The boy had always been weak and delicate. The other children were quite well. There was no history of hæmophilia in the family and no history of rheumatism.

When the patient was first seen after admission he was lying curled up in bed in a very drowsy state. When spoken to he answered in monosyllables and appeared anxious to be left alone. He was inclined to be irritable. The temperature was 100·4° F., the respirations were 28, and the pulse was 120, small, soft, and compressible. He had a very pallid expression and when he slept his breathing was stertorous in character. Blood was continuously oozing from his gums and as a result his breath was exceedingly foul. The teeth were not loose. The heart and lungs were normal as was also the liver. The spleen was not enlarged. Abdominal palpation revealed nothing. The body was covered all over with a purpuric eruption. The spots varied in size from that of a split pea to a pin point and in colour they ranged from a dark purple to a bright red. They did not disappear on pressure. They were most profuse on the front of the chest and abdomen, the only parts free from them being the soles of the feet and the palms of the hands. A few were seen on the face, but not many, but the under surface of the chin and the neck were covered with them. The joints were neither swollen nor painful. With the ophthalmoscope well-marked retinal hæmorrhages could be seen. The bowels were confined; there was no blood in the motions. The urine was of specific gravity 1020 and acid; it contained no blood but a trace of albumin.

During the five days that the boy remained in the hospital his apparent condition continued pretty much the same except that he grew more and more anæmic. The temperature throughout kept remittent, the highest being 104° on Oct 17th; the temperature never at any time fell below 100° till the 20th, the day on which he died, when it was 97°. On the 18th a systolic bruit could be heard over the pulmonary area. In both lungs behind some rhonchi and râles were now audible. A most noticeable feature was the rapid diminution in the number of the red blood cells. On the 17th they averaged 1,680,000 per cubic millimetre; on the 18th, 1,170,000; on the 19th, 600,000; and on the 20th (the day on which he died), 310,000. Any leucocytosis present could not be estimated owing to the great difficulty in getting him to bleed from a skin puncture. On the 19th the patient was getting much weaker and he refused all food. All motions were passed under him; he vomited once. In both motions and vomited matter blood was present. At no time during his illness was blood found in the urine. On the 20th the patient died in the early morning.

Necropsy.—A post-mortem examination was made about 10 hours after death. The body was markedly anæmic, as were all the internal organs. The lungs were small, pale and healthy. The heart was small and well contracted. It presented well-marked hæmorrhages in its walls. The stomach presented numerous hæmorrhages in its mucous membrane. The spleen was normal. The liver had a few hæmorrhages on its upper surface. There was only one kidney, the right kidney being absent. The kidney was lobulated, weighed six ounces, and showed no hæmorrhages. The intestines showed a few scattered hæmorrhages in the mucous membrane. On cultivating some of the blood which was taken from one of the chambers of the heart colonies of streptococci were seen. Cover slip preparations were made and under the microscope they were very well seen.

Remarks by Dr. CURETON.—The above case is interesting from more than one point of view. First the disease appears to have run the course of an ordinary purpura hæmorrhagica until some few days before admission to hospital when the symptoms assumed a much graver aspect with rising temperature, almost continuous hæmorrhage from the nasal and alveolar mucous membrane, attended by delirium and rapid loss of strength, suggesting a general infection of the system through the blood, and giving grounds for the belief expressed by Lætzerich, Cassel, Reihl, and Wilson, that this disease may ultimately be proved to be due to a bacillus. Although the bacteriological examinations made thus far in purpura are not numerous there is little doubt that infection is the essential feature in some forms of this disease, particularly as in the case now recorded where there occurred a sudden onset of the alarming symptoms, high temperature, cerebral symptoms, showing a general systemic infection and running on to a fatal issue. It is to be hoped that further light will be thrown upon purpura as the result of a careful bacteriological examination of the cases and a careful examination of the blood both by the spectroscope and hæmatocytometer.

ROYAL INFIRMARY, LIVERPOOL.

A CASE OF CHRONIC INFECTIVE ENDOCARDITIS TREATED WITH ANTISTREPTOCOCCIC SERUM.

(Under the care of Dr. J. H. ABRAM.)

IN the *Mirror of Hospital Practice* in THE LANCET of Feb. 11th, 1899, we published a case of septicæmia in which injections of antistreptococcic serum were followed by recovery and in which the presence of streptococci in the blood was definitely proved. In the case published below a mixed infection occurred and the injections of antistreptococcic serum were apparently followed by the complete disappearance from the blood of the streptococci. Although the patient died the value of the evidence afforded by the case in favour of the action of the serum is hardly less than if she had recovered. Every case in which the antistreptococcic serum is employed after competent bacteriological examination should be put on record, whatever may have been the issue. For the notes of the case we are indebted to Dr. A. Stanley Griffith, house physician.

A woman, aged 39 years, was admitted into the Royal Infirmary, Liverpool, on August 2nd, 1898, complaining of general weakness, loss of appetite, and occasional swelling around the ankles. Her previous history was good and no history of rheumatism could be elicited. Other symptoms such as diarrhœa, emaciation, and a temperature of 102·5° F. on admission, with physical signs of mitral stenosis, led to the diagnosis of infective endocarditis and in confirmation of this nine days after admission a splenic embolism occurred. The blood was examined and streptococci were found in large numbers. It was then decided that antistreptococcic serum should be tried and 10 cubic centimetres of the serum manufactured by the British Institute of Preventive Medicine were injected into the buttock daily for a fortnight, the only appreciable effect on the patient being a steadying of the temperature and an improved general condition. A week later nine injections of the serum manufactured by the Institut Pasteur de Paris were tried, but with no better result; the temperature again oscillated widely, diarrhœa continued to be obstinate, and general anasarca ensued, death occurring on Oct. 1st from multiple embolism. Post mortem blood cultures were made from the splenic substance and numerous colonies of staphylococci were found but no streptococci.

Remarks by Dr. GRIFFITH.—The chief interest of the above case lies in the later bacteriological examination which seems to confirm the value of the antistreptococcic serum, inasmuch as the streptococci which were present had disappeared, although the concomitant staphylococcic infection proved too serious for the patient's recuperative powers.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Discussion on "Pseudo-tuberculosis."

A MEETING of this society was held on Feb. 21st, the President, Dr. PAYNE, being in the chair.

The PRESIDENT referred to the fund which was being raised as a memorial to the late Professor Kanthack. The laws of the society did not allow of any contribution being made from the funds of the society, but he wished to draw the attention of members to it. The capital is to be invested and Mrs. Kanthack is to receive the interest during her life, the fund ultimately being employed to encourage research. The secretary of the fund is Dr. Drysdale, 25, Welbeck-street.

The PRESIDENT also referred with regret to the death of Professor Rutherford of Edinburgh and of Mr. Thomas Cooke.

Dr. G. SIMS WOODHEAD, in opening the discussion on Pseudo-tuberculosis, stated at the outset that the term "pseudo-tuberculosis" had been responsible for a good deal of misunderstanding and the number of conditions classified under it were so numerous that pseudo-tuberculosis was no longer of the slightest value as a term in classification, for numerous pathogenic conditions, most varied as to appearance and etiology, were described by different writers as pseudo-tuberculosis. Dr. Woodhead first referred to a series of cases which came under his own observation during the investigations carried on for the Royal Commission on Tuberculosis and which were, for the sake of convenience, spoken of at the time as "pseudo-tubercular" and which might undoubtedly have been mistaken for true tuberculosis had not the conditions under which they occurred and the microscopic examination given such definite indications to the contrary. In one case, that of a guinea-pig which *died on the second day after injection of tuberculous meat*, much too early therefore to show tubercle as the result of injection, the following conditions were found: venous congestion of the large intestine and cæcum; enlargement of solitary glands and Peyer's patches with small hæmorrhages into their substance; in these glands in the small intestine were white opaque points, sometimes scattered over the whole glandular patch; the mesenteric glands were slightly enlarged; the liver was mottled with small yellow patches; in the lungs were two yellowish grey points; the spleen was normal; and the mediastinal glands were evidently enlarged. The degenerated patches were much whiter than tuberculous nodules and the breaking down was more complete, so that on microscopic examination one could not make out even the outlines of any cells. No tubercle bacilli could be found in any of the lesions, but micrococci, especially in the form of diplococci, were numerous. As all the other guinea-pigs in the experiment were perfectly free from tubercle it was agreed to look upon it as some mycosis other than tuberculosis. Without having recourse to microscopic examination, however, Dr. Woodhead could not have satisfied himself that it was not a case of tuberculosis. In a couple of guinea-pigs inoculated with raw meat from the same cow small nodules were observed in the spleen resembling infarctions. On microscopic examination these nodules were found to have a central necrotic area of dead cells which had lost their outlines and had become fused into irregular masses. Short bacilli with polar staining, almost like diplococci, were found near the margin; around this central area was a zone of shadowy-looking splenic tissue, whilst outside this again was a distinct capsule of connective tissue and leucocytes. In the case of another guinea-pig injected with artificial tuberculous milk heated to 70° C. for one hour, at which temperature tubercle bacilli are rendered innocuous—at any rate, as regards guinea-pigs—the animal died 11 days after injection. In some adenoid patches there were opaque areas which were found on microscopical examination to consist of tissue in an advanced stage of necrosis and at the margin micro-organisms were found, again in the form of short bacilli with polar staining. In another specimen injected with artificial tuberculous milk, heated as before to 70° C. for ten minutes, the animal was killed 101 days after inoculation, and a small, yellowish nodule was found near the surface of the liver and this was seen to be made up of a large mass of organising connective tissue in which not a single tubercle bacillus could be found. Dr. Woodhead described one or two other conditions which at first sight were mistaken for tuberculous granulations but in which true tuberculous structure or the presence of tubercle bacilli could never be demonstrated. He next proceeded to discuss some conditions found in the lungs of sheep brought to him by a medical officer of health who stated that he had had to confiscate large numbers of sheep showing this condition as tuberculous. Dr. Woodhead at once recognised the condition as what is called in Scotland "hoos"—small glistening pearly grey nodules produced by strongylus filariæ. Microscopical examination showed that the nodules consisted of small nematode worms coiled and surrounded by proliferating connective cells. Here they had a perfectly distinct process and one which should certainly not be called a pseudo-tuberculosis. Dr. Woodhead then called attention to Professor Muir's article on Pseudo-tuberculosis in Birds, where at least six different conditions were referred to as having been described. Professor R. Muir of Dundee described a form in birds which was probably the same as that described by Malassez and Vignal, Nocard and Pfeiffer. Several of these forms of pseudo-tuberculosis had been separated from animals inoculated with material from patients supposed to be suffering from atypical tubercle. In others again the guinea-pigs appeared to have been affected "spontaneously"—i.e., they had contracted the disease quite apart from experimentation. This was a point of considerable importance in connexion with Dr. Woodhead's own observations on pseudo-tuberculosis which evidently occurred, in certain cases at any rate, independently of inoculation, as in the animal that died two days after inoculation, whilst in another of his cases bacilli identical in appearance with those described by Nocard, Muir, and Pfeiffer were found to give rise to this condition on the eleventh day. This corresponded very closely with the condition presented in the experiments of Professor Muir who pointed out that a very marked feature in this special form of pseudo-tuberculosis was that both leucocytes and connective tissue corpuscles undergo a very rapid breaking-down and that caseation and softening both take place at a very early stage, the result being that the centre of a nodule becomes almost purulent rather than caseous. The proliferative changes in both Dr. Woodhead's and Professor Muir's cases were well marked and were confined almost entirely to the periphery of the nodule. There was an absence of giant-cells and the bacilli were usually found near the margin of the caseous centre. This accorded perfectly with what Dr. Woodhead observed in the pseudo-tuberculosis of guinea-pigs described in the Report to the Royal Commission on Tuberculosis. In referring to old cases found in museums labelled "tuberculosis" but which more recent investigators had recognised as being cases of actinomycosis, Dr. Woodhead called attention to a case described by Professor Boyce of Liverpool, which that writer very properly described as "aspergillo-pneumonomycosis," a much better term than that of "aspergillar pseudo-tuberculosis" given by Kotljar to a similar condition. Kotljar divided pseudo-tuberculosis into two groups, those of bacterial origin and those of mycotic etiology, these latter being produced by aspergilli. In comparatively recent times they had passed from an anatomical pseudo-tuberculosis to a pseudo-tuberculosis bacillus. A serious question was opened, however, by the discovery by Frau Rabinowitch in milk, cream, and butter of a bacillus which morphologically, and in its staining reactions, but in little else, was identical with the tubercle bacillus, and they had two positions from which it was absolutely necessary to extricate themselves. They had on the one hand organisms of pseudo-tuberculosis which had the morphological and staining characters of the true tubercle bacillus, but which pathologically appeared to be widely separated from it; whilst on the other hand they had a whole series of lesions which presented certain superficial resemblances to tubercle, but which were not induced by the action of the tubercle bacillus. The protean forms of the histological lesions in tubercle made it difficult to describe any single form as typical. Almost every new tissue at some period of its development might be said to be like some stage of a tuberculous process in the rapid infiltration of leucocytes and even the presence of giant cells. The phenomena of endarteritis obliterans were seen also in many non-tuberculous conditions. Taking the tubercle bacillus as the etiological factor and basis of classification and taking the investigations of comparative pathologists in recent years who had found many lesions to be tubercle which were not previously so recognised Dr. Woodhead thought it very inadvisable that any nomenclature should be brought in which could only ultimately lead to confusion, and he hoped that the discussion would lead to the drawing up of an accurate and comprehensive nomenclature of many of those forms of disease which at present were practically unnamed. "Pseudo-tuberculosis" could no longer be regarded as a pathological entity, and although it might be necessary, owing to the exigencies of use and wont, to retain the term "tuberculosis," that term should be restricted as far as possible to a process which had a distinct etiological factor and they should minimise as much as possible the evil of the term by eliminating altogether such terms as "pseudo-tuberculous processes" or "pseudo-tubercular organisms."

Dr Sidney Martin said that his own personal experience covered much the same ground as that of Dr. Woodhead, being obtained through observations which he made independently for the Royal Commission on Tuberculosis. He had repeatedly met with pseudo tuberculosis or, as he preferred to call it, "bacterial necrosis" in guinea-pigs and rabbits At first he was much troubled to diagnose the condition as the specimens in the liver and spleen so closely resembled those of true tubercle. But the appearances in other organs and the results of cultivation made it clear that they were non-tuberculous. Besides, there was great irregularity in the distribution of the lesions, although in inoculated tubercle there was a characteristically uniform march of infection along the lymphatics to the organs of the thorax and abdomen, and from each centre of infection tubercle bacilli could be demonstrated, and each inoculated into an animal gave rise to true tubercle. Cases of pseudo-tuberculosis were very rare in man, most of the recorded cases being due to some aspergillus. There were three, however, recently published which appeared to be due to some form of streptothrix The first was recorded by Dr Simon Flexner and occurred in a negro, aged 70 years. The chief lesions were in the lungs. The upper lobes were consolidated and there were scattered nodules in the lower lobe of the left lung, the nodules being larger than in true tubercle, and having undergone rapid softening. No cavities had been formed as in phthisis, the softened matter not being expelled. There was also infection of the omentum and peritoneum No tubercle bacilli were discovered and inoculations did not give rise to tubercle On microscopic examination a typical streptothrix was found in all the lesions The second case was recorded by Buchholz The patient was a man, aged 38 years, who had an empyema and consolidation of the lung with formation of cavities. The liquid material in the consolidated lung was traversed by branching hyphae, indicating infection by a streptothrix. No tubercle bacilli were present The third case occurred in a woman. There was cystitis at first and then a number of small tumours appeared on the skin and suppurated. Later consolidation of the lungs occurred, supposed during life to be tuberculous After death no tubercle bacilli were found, but there were branched threads of some streptothrix.

Dr. Washbourn said that it would be advisable to discard the term "pseudo-tuberculosis" as it was misleading. By some observers several bacilli which resembled the tubercle bacillus in morphology and in staining reactions would be called "pseudo-tubercle bacilli" They were of importance from the point of view of clinical diagnosis, for by relying upon a microscopical examination alone they might easily be mistaken for the tubercle bacillus. In the urine pseudo-tubercle bacilli of this nature were by no means uncommon. It was on this account that inoculations were necessary for the diagnosis of tuberculosis of the genito urinary tract. The term "pseudo-tuberculosis" was usually applied in quite a different sense to the above. It was used to denote diseases which resembled tuberculosis in morbid anatomy but which were caused by other organisms than the tubercle bacillus. Of late a large number of such diseases had been described. There were many organisms which produced similar anatomical lesions to those produced by the tubercle bacillus. These organisms were of widely different character. There were bacilli such as the bacillus pseudo-tuberculosis, giving rise to caseating tubercles in many animals; the bacillus pseudo-tuberculosis murium, causing caseating tubercles in mice; and the bacillus pseudo-tuberculosis liquefaciens, causing tubercles in the peritoneum in the human subject; and similar lesions in rabbits There were various kinds of streptothrix such as the one described by Dr. Flexner in the human being. There were also organisms which did not belong to the class of bacteria. A form of mould, the aspergillus, had been described as causing a tuberculous lesion in the human lungs and even nematode worms might produce tubercles consisting of giant cells and epithelioid cells in the lungs of cats and the kidneys of dogs There was a skin disease described by Gilchrist and Stokes which was of especial interest. It resembled lupus vulgaris in its clinical aspect but it was caused, not by the tubercle bacillus, but by a blastomyces which they obtained in pure cultivations and which produced in animals by inoculation tubercles consisting of epithelioid cells and giant cells. It was quite probable that many of the cases of so-called tuberculosis of the skin were due to other organisms than the tubercle bacillus, as in a case seen lately in which tubercle bacilli could not be demonstrated either by microscopical examination or by inoculation. It was quite clear that the lesions caused by the tubercle bacillus were by no means specific, for many organisms might produce exactly the same changes. Again, the lesions produced by the tubercle bacillus were not constant; sometimes there was much caseation with formation of giant cells, while in other cases there was the production of a granulomatous tissue; in fact, the tubercle bacillus and the other pathogenic organisms mentioned obeyed a general law They set up a more or less chronic form of inflammation the character of which depended partly upon the virulence of the organism and partly upon the relative susceptibility of the animal. Thus the same pathogenic organism might produce several types of inflammation and the same type of inflammation might be produced by several pathogenic organisms. The most important lesson to be learnt from this discussion was the importance of making a systematic bacteriological examination of every case in the post-mortem room—a procedure very much neglected in London.

Dr. James Galloway said that Dr. Murray of Glasgow had described a case in which mycosis fungoides and later general infection followed a kick from a sheep. An organism was isolated which appeared to be a streptothrix. Dr. Galloway also referred to two rare skin diseases The first, "xanthoma with giant cells," had been called by Unna "pseudo-tuberculosis of the skin." The disease was infective and usually appeared first on the lower lid. The giant cells were arranged in a layer just beneath the epidermis. In one case several of these tumours formed on the face. No tubercle bacilli could be found in the sections. The second form of skin disease was characterised by the appearance of tumours over the surface of the body in which giant cells were present in very large numbers. They closely resembled sarcomata but after some months they disappeared as rapidly as they had come. It was clear that histological evidence alone could not be relied on for diagnosis, but experimental evidence from inoculation must be forthcoming as well

Dr. Woods Hutchinson had several specimens of the conditions which would come under the heading "pseudo-tuberculosis" which he had obtained from the Zoological Gardens. One was a lung in which the lesion was due to an aspergillus taken from a trumpeter bird and he had met with similar specimens in ducks and parrots. It did not appear to be of a very highly toxic character. The other was a monkey's lung showing what was known in Germany as "worm knots" and which could be seen to consist of a mass of coiled worms, probably either strongyli or filariæ. This monkey also had many thread worms in its peritoneal cavity which did not appear to have given rise to any disturbance.

On the motion of **Mr. Shattock** the discussion was adjourned to March 6th.

HARVEIAN SOCIETY OF LONDON.

Varieties of Eczema and their Treatment.

A MEETING of this society was held on Feb. 16th, Mr. HENRY JULER, President, being in the chair.

Dr. WHITFIELD read a paper on Varieties of Eczema and their Treatment. After pointing out that the *older* classification into idiopathic and symptomatic was based on pure theory and that the other classifications merely indicated stages in the process of the regions attacked he proceeded to examine the evidence on which Unna's variety of seborrhœic eczema was based. After excluding psoriasis and simple pityriasis of the scalp the question was whether anything remained. This question he answered in the affirmative and defined seborrhœic eczema as a disease starting in the follicles, afterwards possibly attacking parts which were destitute of follicles, having a well-defined border to the edges of the patches and a strong tendency to serpiginous advance. Audry's case of seborrhœic eczema occurring on scar tissue was then discussed in order to show that although seborrhœic eczema could occur on areas of skin which possessed neither sebaceous nor sweat glands, nevertheless it flourished much more easily on normal skin. The fact of Audry having succeeded in inoculating the disease from one part of the patient to another was also mentioned as tending to show that the disease was parasitic in origin. Dr. Whitfield then shortly mentioned the other varieties of eczema which were supposed to own a parasitic origin—namely, the eczema folliculorum of Morris, that of Neisser, the eczema mycoticum of Hans Hebra, and the eczema circumscriptum of Crocker. He considered that the clinical evidence in favour of these diseases being due to organisms was rather strong but that until the different microbes had been determined so that the diseases could be properly classified, as had been done in ringworm, it was more convenient to group them all under the heading of "seborrhœic eczema." Passing on to the so-called simple eczema Dr. Whitfield said that there were two main opinions as to the origin of the disease, one of which was that the disease was an outward manifestation of a constitutional disorder and the other that it was due to some local irritant. He then proceeded to inquire what evidence there was of the relation of the disease to gout and quoted Garrod's paper on the subject to show that although gouty patients were undoubtedly more prone to the disease there were no distinguishing points to indicate an eczema of gouty origin from that due to any other cause. Colombini's researches on the toxicity of the urine in acute, weeping, and chronic dry eczema were then referred to and it was pointed out that as far as they went they were rather against the supposition of a toxæmia as the cause of acute eczema. The supposed danger of the sudden suppression of discharging rashes was then entered into and although there were one or two cases on record which seemed to show with reasonable certainty that the attempts at curing an extensive eczema had been followed by untoward results the accident was undoubtedly one of extreme rarity. On the other hand, a case had been published of a child who had died from septic infection from a wide-spread eczema and this danger seemed a much more important one than the supposed production of metastases. The parasitic theory of simple eczema was then referred to and was considered as entirely unproved. The recent papers of Leredde and Török were quoted and the incompleteness of the arguments for the bacteriological origin of eczema were pointed out. The great confusion appeared to be due to the wrong use of terms and it was strongly to be deprecated that observers did not more accurately describe the lesions about which they were writing. The probability was that there were at least two diseases, one of which was of entirely unknown origin and might be called simple eczema and the other was probably of parasitic origin, although the parasite was at present unknown, and this was the disease to which the term "seborrhœic eczema" might be restricted. Turning to the treatment of eczema, it was pointed out that in the supposed parasitic variety antiparasitic remedies could be used much more boldly from the start than in the simple variety. In the treatment of acute weeping eczema it was best to treat the skin with soothing lotions which had just sufficient antiseptic power to inhibit the growth of any accidental contamination with cocci which would be sure to occur. Later, when the discharge had ceased, ointments could be used and it was important that they should be of a sufficiently solid consistency not to run into the covering and leave the surface dry. Later resort might be had to stimulating applications to patches which proved resistant and it had even been recommended to scarify very old and thickened parts.

Dr. GALLOWAY remarked that he thought that Dr. Whitfield had taken an appropriate opportunity for protesting against the too easily accepted hypothesis of the bacterial origin of eczema and he especially agreed with Dr. Whitfield in protesting that no special coccus such as the "morococcus" had been discovered to act as a specific organism. If anyone took the trouble to examine carefully the evidence on which Dr. Unna had based his description of his morococcus as the specific cause of seborrhœic eczema it would readily be seen how slight it was. In the case which Dr. Unna demonstrated before the Hamburg Medical Society, in which he had produced what he called his inoculation vesicle from pure cultures of this "white" coccus, the important clinical fact outstanding was that the lesion so produced was not eczema at all but something much more closely resembling impetigo. From the time of this demonstration this coccus had been quoted by Unna and many of his disciples as the specific organism in his large group of seborrhœic eczema. About the same time as Dr. Unna Professor Welch of the Johns Hopkins University had published his observations on the bacteriology of the skin. He showed that the organism which he called the "staphylococcus epidermalis albus" was a constant denizen in the skin, where it lived a saprophytic existence and appeared to produce no pathogenic effects. No sufficient evidence is on record to prove that the morococcus is not an organism of the same class, and there is much to support the view that it is simply a saprophyte. One could not help coming to the conclusion that if any organism does produce seborrhœic eczema, at any rate it is not the morococcus. Dr. Galloway felt inclined to look upon eczema as the ordinary inflammatory reaction of the skin to many varieties of irritation. There was little doubt that amongst these various irritants bacteria exercised considerable influence. The type of eczema which appeared to be of parasitic origin was the seborrhœic variety, but he wished to emphasise the fact that the evidence in favour of this at the present time is almost completely clinical and has no definite bacteriological support. It is most important, however, from the practical point of view, to recognise the fact that these varieties exist, as the use of appropriate remedies must be determined by the exactitude with which we are able to define the causation of any individual attack. The value which has long been appreciated of antiseptic remedies in the treatment of eczema depends upon the fact that certain manifestations of it are produced by parasitic influence. The more clear we are, therefore, in our recognition of the found facts of eczema produced or influenced by micro-organisms, the more successful will our treatment of the clinical varieties become.

Dr. ALFRED EDDOWES said that he found Dr. Unna's "bottle" bacillus so frequently in cases of seborrhœa that he was disposed to think with Dr. Unna that it probably had a causal relation to the disease. But this was hardly the time to deal with the bacteriology of eczema in detail. He thought the word "eczema" should mean a condition, not a definite disease, unless the word were qualified with an adjective. It was useful clinically to speak of seborrhœic eczema, impetiginous eczema, tuberculous eczema, &c. He had accidentally inoculated two of his nail-beds by handling a patch of impetiginous eczema and had obtained pure cultures of the staphylococcus aureus from the resulting subungual abscesses. Dr. Sims Woodhead referred to the fact in a paper in THE LANCET some years ago. He showed a photograph of a case of eczema contracted probably from a school thimble and expressed his opinion that this slowly advancing form of dry eczema was of tuberculous nature. He also showed a photograph to illustrate what he called "sympathetic eczema." He had painted a chronic, stationary, sharply defined patch of eczema on the right forearm of a gouty (?) patient with strong iodine tincture. On the next week an exactly symmetrical patch of eczema appeared on the left forearm. In attempting to explain this remarkable reaction he suggested that the vaso-motor system, like the muscular system, of nerves was so linked together that a sufficient stimulus to the centres could produce bilateral response, as was observed in the involuntary, genuine, bilateral laugh of the hemiplegic.

As for treatment there was much that might be said. It was easy to lay down certain definite principles which were always useful. We should keep in mind the physiological state of normal skin. We must dry a wet skin and grease a dry skin. Dabbing with spirit and dusting with powder answered the first requirement and ointments the latter, while pastes occupied the intermediate place and were most valuable. Take, for instance, a bad case of "scald head," eczema of scalp, in a child. One thorough dressing with a paste such as Lassar's frequently left nothing more to be done by the medical man or the mother for a whole week, and at once made such a case greatly better and quite manageable. He was surprised to hear Dr. Whitfield say that he did not find pastes of great service.

Dr. **BEZLY THORNE** said that he attached more importance to toxic conditions of the blood in relation to eczema than Dr. Whitfield was disposed to accord to them, and that he could not regard as valid the argument that if the kidneys were sound they must be innocent of mischief, because they might by habit and regimen be inhibited *from performance* of their normal function. He gave as an instance the case of a lady who had for seven years suffered from a severe form of eczema palmaris with inflammation of the matrices and deformity of the nails, amounting in the index fingers to partial destruction. The total daily ingestion of fluids, consisting of tea, coffee, and claret, barely amounted to seven-eighths of a pint. In three weeks the disease was arrested by the use of an ointment containing ammoniated mercury, of a mixture containing grain doses of potassium iodide, and by the ingestion of two pints of water daily. This result which had been maintained up to the present time was mainly if not entirely due, Dr. Thorne felt convinced, to the water which had restored to the kidneys the power of promoting the purity of the blood. He added that he entertained no fear of the local effect of salt water, as in every instance in which patients affected with *seborrhœic eczema had, under his observation, undergone a course* of saline baths the skin had become sound before the termination of the treatment. That result might possibly be attributed to the diuresis which the baths in all cases induced.

Dr. **WHITFIELD** replied.

LIVERPOOL MEDICAL INSTITUTION.

Anatomy of the Pineal Gland.—Some Points in the Structure of the Dental Tissues.—Exhibition of Specimens.

A MEETING of the Pathological and Microscopical Section of this society was held on Feb. 16th, Mr. F. T. **PAUL** being in the chair.

Dr **ALFRED W. CAMPBELL** read a paper on the Anatomy of the Pineal Gland and on Certain Pathological Conditions arising in it. He carefully described the naked-eye and microscopical characters of this organ He had examined a large number of pineal glands and showed that in all there existed either a definite central cavity—a ventricle—or else collection *of specialised tissue resembling* neuroglia. When the cavity was present it was surrounded by similar tissue. In some pineal glands he had found pigmented elements similar to those found in the retina. He also described several pathological conditions which he had found in the pineal glands of insane patients. (The paper was illustrated by anatomical and microscopical preparations and by some beautiful drawings and numerous lantern slides.)—Mr. **PAUL**, Mr. **LARKIN**, and Dr. **GRUNBAUM** discussed the paper and Dr. **CAMPBELL** replied.

Mr. F. T. **PAUL** read a note on Some Points in the Structure of the Dental Tissues and illustrated his remarks by some microscopic specimens and lantern photographic transparencies.—This note was discussed by Mr. **RUSHTON PARKER**, Mr. **LARKIN**, Dr. **GRÜNBAUM**, Dr. **MONSARRAT**, and Dr. **BUCHANAN**.

Mr. C. G. **LEE** showed an Epithelioma of the Auricle and discussed its frequency and relative malignancy in this situation.

Mr. **THELWALL THOMAS** showed a Testicle with part of the Spermatic Cord attached into which an extensive hæmorrhage had occurred. It was removed from a man 32 years of age. The swelling appeared spontaneously. There was great pain and the testicle was drawn up to the external abdominal ring. The microscope showed no new growth.

Mr. **LARKIN** showed for Dr. **JOSEPH WALKER** a large Pedunculated Soft Fibroid of the Labium Majus removed from a middle-aged woman.

Mr. **NEWBOLT** *showed the Left Humerus* of a boy, aged 16 years, the upper end of which was occupied by a round-celled sarcoma. Amputation was done 10 months ago and as yet there was no recurrence.

Dr. G. G. **STOPFORD TAYLOR** showed a Microscopic Section of an Epithelioma of a Lupus Scar. The growth was situated on the left side of the neck of a man, aged 46 years, who had suffered from lupus for 40 years.

Mr. **DOUGLAS CRAWFORD** showed some Microscopic Sections of a portion of an Enlarged Prostate. The part had been removed by suprapubic prostatectomy for urinary obstruction. The patient was 54 years of age and had already had bilateral vasectomy performed with no permanent benefit. The section was much more glandular than was usual.

Dr. **ALEXANDER** showed the Brain of a Male Epileptic, aged 20 years. There was complete atrophy of the left temporo-sphenoidal lobe and the posterior parts of the frontal convolutions. The fits began in and affected chiefly the right side of the body. The right leg was permanently partially paralysed, but the paralysis was always much increased after a fit.

Dr. **BUCHANAN** showed specimens illustrating the Structure of Molluscum Contagiosum.

A short discussion followed in which several members took part.

PLYMOUTH MEDICAL SOCIETY.—A meeting of this society was held on Feb. 11th, Mr. M. H. Bulteel, President, being in the chair.—Mr. F. Everard Row read a paper on the Diagnosis and Treatment of Surgical Diseases of the Kidneys with especial reference to Stone and Tubercle. The *chief symptoms for the diagnosis of stone and tubercle were,* he said, (*a*) pain, (*b*) the condition of the urine, (*c*) enlargement or otherwise of the kidney, and (*d*) reflex symptoms such as vomiting and retraction of the testicle. The pain in both diseases was liable to the greatest possible variation both in intensity and situation, but more especially so in calculus, and was due to several causes, as, for instance, to the passage of either a stone or débris of new growth down the ureter producing what was known as renal colic. The pain of stone was more frequently reflected and paroxysmal and was often referred to the neck of the bladder to which attention was drawn instead of the true cause, but may be reflected anywhere from the shoulder to the neck. Large stones embedded in the substance of the kidney as a rule caused less pain than smaller stones, which might be free in the pelvis of the kidney or become impacted in the ureter. Hæmaturia was a frequent accompaniment of stone, but was not so frequent in tubercle. Pus was present in both tubercle and stone; but in tubercle it appeared early in the disease; in stone it was not present unless pyelitis had been set up by the irritation of the foreign body. Unless a kidney was much enlarged it was not easy to palpate it. When the enlargement was due to calculi crepitus might be felt by placing one hand in the loin and pressing the kidney towards the fingers of the other on the abdomen. As to the reflex symptoms, vomiting due to renal colic did not differ from that due to other causes. Retraction of the testicle was one of the most important features in renal stone. In tuberculous disease early nephrectomy afforded the best chance of cure. When disease of the other kidney was obvious or even uncertain nephrectomy was a futile or dangerous proceeding and nephrotomy and drainage should be resorted to. In calculus the treatment resolved itself into palliative and operative. Palliative treatment consisted in relieving the pain of renal colic by hot baths, fomentations, and anodyne injections. The operative treatment consisted of exposing and puncturing the kidney and if a stone was found incising the organ and removing the foreign body. If the kidney was disorganised by a number of stones and by pyelitis and the other kidney was known to be present and in fair working order either by cystoscopic examination or by an incision in the loin nephrectomy was indicated. In order to determine this latter point abdominal nephrectomy was taking the place of the lumbar method.—Cases and specimens were exhibited by Mr. Row, Mr. Woollcombe, Dr. Pethybridge, Dr. Rider, and Mr. J. R. Rolston.—A communication was read from the Corporate and Medical Reform Association and on the motion of Dr. Shaw, seconded by Mr. J. R. Rolston, the following resolution was carried *nem. con.*: "That this meeting of the Plymouth Medical Society begs to accord to the Direct Representatives of the medical profession on the General Medical Council and those who supported them a hearty vote of thanks for the action they have taken on the question of Illegal Certificates of Proficiency in departments of medicine, surgery, or midwifery."—A communication was read from the Medical Institution of Liverpool on the amendment of the Vaccination Act, 1898, but it was decided to take no action in the matter at present.

OXFORD MEDICAL SOCIETY.—The fourth ordinary meeting of this society was held on Feb. 10th in the Anatomical Theatre at 8.30 P.M., Mr. H. P. Symonds, President, being in the chair.—Mr. Farmer showed specimens of (1) Hour-glass Stomach from the body of a man; (2) Vermiform Appendix lying in the Post cæcal Fossa and attached firmly to the intestine; and (3) a Skull with a Clean-cut Perforation through the Mastoid Process exposing the antrum. No history attached to the specimen, but the opening suggested the trephine.—Mr. Winkfield read a paper on the Use of Antitoxin in Diphtheria. Reviewing the mortality returns of this disease in Oxford during the past 10 years he showed that there had been a striking decrease in mortality since the discovery of antitoxin (from 34·3 per cent. before 1894 to 14·17 per cent., the present rate of mortality). He laid stress on the fact that in no case did laryngeal symptoms set in after injection of antitoxin, while in several cases its timely use rendered tracheotomy unnecessary. He used Behring's serum, giving 600 units as an ordinary dose in mild cases. For more severe cases 1000 units were recommended, while 1500 units were regarded as a "treble dose." For prophylactic purposes 200 units were sufficient. He rarely had occasion to repeat the injections. After one injection the membrane was noticed to curl up at the edges and to clear off rapidly, the glandular swellings subsided, and the throat was usually clear within a week. He noticed copious perspiration and a tendency to faintness after injection and usually kept the child lying down for three weeks. A rash had occurred occasionally, but he had had no kidney complication.—Mr. Parker read a paper on Training in Relation to Athletics. He drew attention to two points—(1) regular and graduated exercise and (2) diet. These two methods he stated to have been in vogue since ancient times, especially among the Greek athletes. Their diet was farinaceous at first, but meat was substituted later. He advocated that the chief exercise in training should be that for which the athlete was preparing. By gradually increasing the amount of work done the body might be trained to undertake tasks which at first would have been impossible. Therefore, in those athletics, such as rowing, which required severe and prolonged exertion the training should be long and gradual. Rowing in untrained men was distinctly harmful. Mr. Parker insisted on the importance of training on individual merits. He deprecated the sudden change from an ordinary diet to an almost entirely proteid one. Since physiologists showed that muscular exertion, unless carried to exhaustion, did not involve increased nitrogenous waste he advised that the bulk of food taken by an athlete in condition should be of the carbohydrate order. He discussed the question of "second wind" and "staleness." He regarded "second wind" as either the result of the readjustment of the systemic and pulmonary circulation or as due to the toxic products of muscular action acting on the respiratory centre. "Staleness" he thought was probably an auto-intoxication.—An interesting discussion followed.

IPSWICH CLINICAL SOCIETY.—A meeting of this society was held on Feb. 9th, Mr. S. O. Eades, President, being in the chair.—The President showed a patient from whom a large Myxo-sarcoma of the Parotid Gland had been removed. The patient was a man, aged 46 years, and the growth first occurred at the age of 21 years; it was removed by Mr. Christopher Heath when the patient was 27 years of age; it recurred and was removed a second time at the age of 36 years, since which time—i.e., ten years ago—there had been no sign of recurrence. Photographs of the case at different periods were also shown.—Mr. C. K. Moseley read notes of a severe case of Purpura Hæmorrhagica in a girl aged 11 years. Bleeding from the gums was first noticed and hæmaturia and constant vomiting were marked symptoms in the case. Jaundice supervened, but the child eventually made a complete recovery. Mr. Moseley had found turpentine a most efficacious drug in this condition.—Mr. Moseley also read notes of a case of Retention of Urine in an old man, aged 80 years, the subject of right-sided hemiplegia. He suddenly passed a large quantity of pus and this was followed by retention. It was found impossible to pass an instrument into the bladder and after aspirating once or twice Mr. Moseley performed suprapubic cystotomy. He was unable to pass a bougie into the urethra from the bladder and the patient now had a permanent urinary fistula kept open by means of a tube and refused any further surgical interference. There was no prostatic enlargement and the cause of the retention was probably a peri-urethral abscess.—Dr. Brown showed a specimen of Sarcoma of the Bladder with Secondary Growths in the Liver. The patient was suspected to be suffering from stone in the kidney and died suddenly from hæmoptysis.—Dr. Brown also mentioned a case of Hæmaturia in a woman five months pregnant in which the diagnosis was obscure. Labour was induced and complete recovery rapidly resulted.—Dr. Ward read notes of a case of Sarcoma of the Bladder in which the growth was found to be too extensive for removal. The patient died from septic meningitis two days after operation.—A prolonged discussion took place on the subject of the Hospital Accommodation in Ipswich for infectious cases and especially for cases of diphtheria.—Mr. Corfe stated that since the last meeting of the society the board of management of the East Suffolk and Ipswich Hospital had decided to admit to the wards cases of diphtheria requiring tracheotomy.—Mr. G. S. Elliston, medical officer of health, thought that every medical practitioner should use the diphtheria antitoxin before sending cases to the fever hospital.—The following resolution was unanimously passed: "That in the opinion of the members of the Ipswich Clinical Society the present accommodation at the infectious hospital of this town is insufficient and that Mr. G. S. Elliston, medical officer of health, be asked to approach the Health Committee to provide proper room for increased treatment, with special reference to the desirability for accommodation and treatment of persons suffering from diphtheria."

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in the University College, Dundee, on Feb. 3rd, Dr. McGillivray being in the chair.—Professor Kynoch showed a Solid Tumour of the Ovary associated with a Multilocular Cyst weighing seven and a half pounds removed on account of rapid ascites. The liver was cirrhotic and so the cause of the ascites was doubtful. Reference was made to two other cases of solid ovarian tumours.—Dr. Halley showed a uterus from a case of Ruptured Extra-uterine Gestation and with a second fœtus in the uterus. The patient, aged 29 years, was admitted to the Royal Infirmary, Dundee, in an extremely collapsed condition suffering severe pain which had come on suddenly eight hours previously. She stated that she was seven weeks pregnant. On opening the abdomen it was found to be filled with blood which was seen to be escaping from a rupture in the right Fallopian tube just external to its junction with the uterus, which was noticed to be somewhat enlarged. The Fallopian tube was ligatured as rapidly as possible and the wound closed. The patient scarcely rallied at all from the excessive bleeding before the operation and died in 10 hours.—Dr. J. W. Miller read notes of a case of Lateral Sclerosis which he had had under his care 20 years ago. The illness commenced with a sudden attack of abdominal pain which recurred at intervals and was followed later by tetanic contractions, at first in the right arm and later extending. These tetanic spasms were the most marked symptom and were easily induced. The patient lived three and a half years, having been bedridden three months before her death with paralysis of the upper and lower extremities but having no impairment of the intellect.—Professor Stalker gave an account of a case of Bright's Disease with Uræmia which had been treated by venesection with the result that the convulsions ceased. When any signs of impending uræmia showed themselves venesection was performed and the signs disappeared and the convulsions were prevented. After four venesections the headaches did not recur but the daily amount of urine still remained low. This improved under internal administration of pilocarpine and tapping of the abdomen for ascites. Other remedies had failed and the patient was now doing well. Professor

Stalker referred to a similar case which his colleague Dr. Whyte had treated by venesection with the result that the fits ceased. He thought that venesection was of distinct benefit in cases of kidney disease where there was very little dropsy and persistent headache and also in some cases in which cardiac distress was at its worst.—Mr. Steele Moon quoted two cases in which he had performed venesection with improvement when other remedies had failed, one of Bronchitis with marked dyspnœa and the other of Uræmia.—Dr. J. W. Miller, Professor Kynoch, and Dr. Duncan also spoke.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 15th, the President, Mr. T. Davies Pryce, being in the chair.—Mr. A. R. Anderson read a paper on the Radical Cure of Hernia, based on 117 cases in which he had operated for the radical cure of inguinal hernia, to which variety he confined his remarks. These included strangulated cases in which this operation had been done There were four deaths, two occurring in the strangulated cases. The deaths in the non-strangulated cases were one from bronchitis after ether and one from cellulitis of the abdominal wall in a fat, middle-aged man with a bulky, irreducible hernia containing large intestine. Of late Mr Anderson had exclusively performed the Bassini-Halstead operation which he considered as the best. 60 cases had been operated on by this method without a single relapse as far as he was aware. He said that his results would not be accepted by many surgeons as it was only three years since he commenced to perform this operation, but he considered that experience of Bassini's operation would remove the doubt which was felt by some as to the probability of a radical cure being effected by operative means. He agreed that this doubt still existed for all operations which left the cord in the canal and did not obliterate as well as close it. He did not admit that five years must elapse before a Bassini's operation could be accepted as effecting a radical cure; on the contrary, an examination of the dense resulting cicatrix occupying the site of what was once the inguinal canal conveyed the conviction from the first that the patient would never again be ruptured at this spot. Mr. Anderson described the operation which he was in the habit of performing and discussed the questions of the wearing of a truss after operation and the advisability of operating in young children. He never ordered a truss after Bassini's operation unless the circumstances were altogether exceptional. With respect to operating on children he said it should be adopted as the routine treatment at any age in the children of the poor and in the children of the well-to-do in all cases of complete scrotal hernia. Among the children of the former it was impossible to ensure accurate fitting of trusses or pads and very difficult amongst those of the latter, whilst the absence of mortality and the tendency towards cure rendered the operation at that period of life one of the most successful in surgery. Mr Anderson showed two cases in which he had recently operated—viz., a man, aged 25 years, and a child, aged one and a half years, and directed attention to the obliteration of the canal, the absence of bulging, and the firmness of the scar.—Mr. Willis showed a man, aged 18 years, suffering from Dyspnœa of many years' duration caused by an unilateral enlargement of the thyroid which he suggested was an adenoma and proposed its enucleation.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held on Feb. 9th, Dr. James Murphy being in the chair.—Dr. G. V. Miller exhibited a case of Recurrent Intra-ocular Hæmorrhage. The patient was a man aged 28 years. Five months ago he observed a black spot before the right eye which gradually increased in size and in four hours the eye had become totally blind. 15 years before, and again five years ago, the patient had noticed a similar fly like spot before the same eye followed by dimness of vision lasting about a fortnight. There was no history of injury or any discoverable cause, though the patient had been the subject of frequent attacks of epistaxis. At the onset of the present attack there was evidence of extensive intra-ocular hæmorrhage, either sub-hyaloid or between the retina and choroid, the media at that time being clear. At a later date, however, the hæmorrhage had evidently burst into the vitreous.—Dr. T. Oliver brought forward a man suffering from Plastic Bronchitis and exhibited several large and very perfect Bronchial Casts which the patient had expectorated. The history extended over a period of four years. The casts in this case were solid and not tubular. No cause had been discovered.—Dr. G. R. Murray showed the following patients: 1. A case of Unilateral Glosso-laryngeal Paralysis in a man aged 46 years. The lesion was not considered to be central but rather due to a localised syphilitic meningitis involving the roots of the spinal accessory and hypoglossal nerves. 2. A case of Progressive Muscular Atrophy in a woman aged 43 years. 3. A case of Locomotor Ataxy with Goitre. This patient, a man aged 52 years, had a definite history of syphilis. 4. A Cretin. This patient, a woman aged 23 years, showed distinct though slight evidences of cretinism. There was still apparently a considerable amount of active thyroid tissue.—Dr. Hume exhibited three cases of Operation on the Stomach.—Mr. Williamson showed a boy upon whom he had recently operated for Acute Infective Epiphysitis of the Upper End of the Humerus.

BIRKENHEAD MEDICAL SOCIETY.—A meeting of this society was held on Feb. 10th, Mr. H. Nazeby Harrington, President, being in the chair.—The following resolution was unanimously adopted: "That the fee of one guinea should be charged for filling up certificates under the Workmen's Compensation Act and that hospital authorities should be asked to allow their house surgeons to charge the same"—Dr. James Barr (Liverpool) read a paper on Meningitis. He entered minutely into the etiology, pathology, and symptoms of the different types and held out a much more favourable prognosis than was usually given in such cases. In the way of drugs his sheet-anchor was opium freely administered. Latterly he had been using morphia almost exclusively in quantities varying from about two up to six grains daily. In very young children he started with a twentieth of a grain every three hours and rapidly increased the quantity so as to keep the child constantly under the action of the drug. With children of six or seven years of age he began with a sixth of a grain; over that age he generally gave the drug hypodermically. In a very successful case in an adult he administered six grains daily for a fortnight. He said that if the treatment was commenced early before there was any effusion into the ventricles a patient suffering from meningitis would not be easily poisoned with opium. He did not, however, look upon opium as a specific for this or any other disease. The bowels were kept open and as occasion required various remedies were used to check vomiting, while almost as a routine internal antiseptics such as salol, benzo-naphthol, &c., were used.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Feb. 17th, the President, Mr. D. H. Goodsall, being in the chair.—Mr. A. Quarry Silcock read notes of a case of a boy, aged 18 years, who had been Run Over by a Cart; he had been laid up with abdominal pain for five weeks and his left hypochondrium was swollen and dull to percussion anteriorly and resonant posteriorly. The abdomen being opened a cyst resembling an ovarian cyst was found to be inseparably fixed to the stomach. Accordingly the cyst was incised and drained, and its edges were stitched to the abdominal wound. The contained fluid was blood-stained and alkaline, its specific gravity was 1018, and it had lymph corpuscles and granules; there was no ferment present. He regarded this as a mesenteric cyst resulting from the injury.—Dr. A. Morison showed a series of cases of Heart Disease and said that belladonna was preferable to digitalis in simple aortic incompetence, though if that state were supplemented by mitral incompetence digitalis was useful. Bradycardia, as tachycardia, had (1) a nervous origin and (2) a cardiac origin. In the latter case treatment by drugs failed but in the former it was efficient. The combination of digitalis and strophanthus excelled either alone. The value of arsenic in heart cases on account of its improving nerve tone should be borne in mind.—A general discussion followed.

NEWPORT MEDICAL SOCIETY.—A meeting of this society was held on Feb. 1st, the President, Mr. H. E. Williams, being in the chair.—Mr. O. W. Morgan showed a case of Cystic Tumour of the Neck.—Mr. H. B. Seddon read notes and showed a case of Raynaud's Disease.—Mr. J. Lynn Thomas read a short paper on Thyroidectomy with and without General Anæsthesia and showed a specimen of Tumour Removed. Mr. [illegible] form of Scissors for Conveni[illegible] [illegible]ry read the report of the committee referring to the proposed lending library of the society with draft of rules. The same were discussed and agreed to.

Reviews and Notices of Books.

George Harley, F.R.S., or the Life of a London Physician. Edited by Mrs. ALEC TWEEDIE. London: The Scientific Press, Limited. 1899. Price 16s.

THE late Dr. George Harley was a well-known physician and as he has been dead only a little over a year both his name and his work will be familiar to our readers. The detailed story of his life is largely compiled by his daughter, Mrs. Tweedie, from diaries or autobiographical memoranda and is designed to please and inform a lay public rather than a medical one.

George Harley's life was not exactly typical of the life of a London physician, so that Mrs. Tweedie's sub-title is to some extent misleading. He was born in Haddington and educated in Edinburgh, Paris, and Vienna, and certain German Universities. He did not come to London until his twenty-sixth year, when he was appointed Assistant Director of the Anatomical Museum of University College, mainly, it would appear, through the intervention of the all-powerful Sharpey who recognised the breadth of his biological work. During his student days at Paris he went considerably into certain classes of French society and, being a French scholar was able to appreciate the things that he saw and heard and to reap much more benefit from a sojourn in a foreign university than accrues to the usual British student. From the knowledge of French manners thus acquired he was able to write down in his diary some interesting observations concerning Napoleon III., the infamous *coup d'état*, and the vexed question of whether that curious ruler was or was not a coward. On obtaining a *locus standi* in London George Harley appears to have made his way rapidly both in society, particularly of what we may call the upper Bohemian sort, and in the world of science. His methods were original and thorough and his power of work was appreciated by his contemporaries as well as by his seniors. He was early elected a member or corresponding member of many learned societies, a Fellow of the Royal College of Physicians of London, and in 1865 a Fellow of the Royal Society. At University College he was a successful lecturer, holding his own in such good company as Sir William Jenner, Sir John Erichsen, Sir J. Russell Reynolds, Dr. Charlton Bastian (whose name the author misspells), Sir Alfred Garrod, and Dr. W. Hayle Walshe. (Is this distinguished physician the person whom the author alludes to as "Mr. Walsh, the eminent surgeon"?) At University College Dr. Harley made microscopic studies his passion and to overwork at the microscope must be attributed a terrible physical calamity which fell upon him in 1866. He became suddenly blind under circumstances which have been described by himself in the columns of THE LANCET.[1] For nine months he lived in total darkness—not simply in a darkened room but in total darkness—and during that time and the period immediately following he kept a record of the sensations and his acquired ability to see in the dark, the time that visual impressions lasted, and the order in which appreciation of colours returned. For an ardent worker and an ambitious man still in the prime of life thus to behave in the face of such an overwhelming calamity as total blindness is a signal proof of courage. It was two years and a day before he was able to take up his work again and he then had to wear darkened glasses, but as time went on he recovered his powers of sight.

The most interesting chapters in the book to medical men are those near the end dealing with Dr. Harley's scientific and other hobbies. We do not in the least agree with his arguments in favour of a simplification of English spelling and we consider his views with regard to champagne to be as unsound in theory as in practice they are contrary to general experience; but we can at the same time appreciate the activity of mind which impelled him to make investigations for himself at first hand in so many by-paths of science. On the whole the book is well done, though Mrs. Tweedie should have been more careful in certain of her expressions lest she should be assuming for Dr. Harley a position as a scientific pioneer to which he has no right and which he certainly would never have claimed for himself. We point this out with reluctance because the feelings which have in a few passages betrayed her into a phraseology against which we must protest do credit to her affection. Such sentences as, "Medical science was literally groping in the dark when George Harley first came to London," "In the days when my father came to London *anatomy and physiology* were taught together," "The proof that spontaneous generation did not exist led my father's old friend Lord Lister," &c., "The discovery of anæsthesia also came prominently before the public in George Harley's lifetime," either mean nothing or they imply that the late Dr. Harley played a foremost part, not only in the evolution of scientific medicine—where some claim might be made out—but in the discoveries of antiseptic methods and of anæsthetics. Mrs. Tweedie we acquit of intentionally misleading her readers, but her book is written for the laity who might easily receive wrong impressions from her habit of grouping vast scientific developments (if only loosely) round her father's name. Nor do we like the expression "George Harley of Harley-street," the Christian name making the address unnecessary; while the statements that Dr. Harley chose the house in the street "because of family associations" and when medical men were scarce in the neighbourhood are not convincing. There were upwards of 20 medical men living in Harley-street a year before Dr. Harley went there. But we do not desire to lay undue stress upon the blemishes in taste or small errors in fact which have caught our attention in the perusal of a book that is pious in its aims and spirited in its performance.

Manual of Operative Surgery. By H. J. WARING, M.S., M.B., B.Sc. Lond., F.R.C.S. Eng., Demonstrator of Operative Surgery and Surgical Registrar, late Senior Demonstrator of Anatomy, St. Bartholomew's Hospital; Surgeon to the Metropolitan Hospital, &c. Edinburgh and London: Young J. Pentland. 1898. Pp. xxvi.-661. Price 12s. 6d.

IT must always be a difficult matter to write a treatise on operative surgery which will prove satisfactory in every respect; for if the work be intended as a guide to the student in the operations which he performs on the cadaver it will hardly prove of much practical value to the operating surgeon. We must confess that the difficulties which we have indicated have been overcome in a very able manner by Mr. Waring and as a result we find a small volume which gives a complete account of all the operations which are usually performed by students in a course of operative surgery and in addition many operations are described which are practically never performed on the dead body; in fact, the work forms a complete manual for the student of the ordinary and of many of the rarer operations of surgery.

The first chapter contains an account of the preparations which the patient should undergo both with regard to asepsis and to anæsthesia. Then follows an account of the methods in which a knife should be held in making incisions through the skin and other structures An account is given of the various methods of suturing, but the "continuous suture represented is hardly so useful as the "buttonhole" suture which holds together better the edges of the skin We cannot concur in the opinion expressed that a "granny' knot is more liable to slip than a 'reef' This is, indeed, what is usually taught but experiment will readily show it to be erroneous The reason for the preference shown by sailors for the reef knot is that it can be much more readily "upset than the "granny'

---

[1] Auto-clinical Remarks on Injury to the Retina from Overwork with the Microscope, by George Harley, M.D., F.R.S. THE LANCET, Feb. 1st, 1868.

The order in which the operations are taken may appear at first sight to be somewhat peculiar, it is that which is adopted in the practical classes in operative surgery at St Bartholomew s Hospital and it has been found to be most useful when only a small number of bodies are available for operative surgery After this explanation we need not feel surprise that the next chapter describes the operation upon the stomach and the intestines Students often experience a difficulty in comprehending the method of application of Lembert s and other intestinal sutures but no one could fail to understand after seeing the excellent diagrams which the author has supplied The description of each operation, not only in this section but also in all the others, is preceded by an account of the chief indications for it

It is difficult to say which part of the work is best where all is so good, but we are inclined to think that the chapter dealing with the surgery of the skull and brain is the most satisfactory of all The account of the ligature of arteries in their continuity and the description of the amputations and excisions which are usually practised are clear In speaking of excision of the shoulder why does Mr Waring call the anterior incision which commences near the top of the coracoid process the "external incision?

Mr Jessop has contributed a short chapter on Ophthalmic Operations which contains all that is needed by the ordinary student

We consider that Mr Waring has executed his task with much success and his work should prove a popular handbook of operative surgery for students, and to that end we heartily commend it

---

LIBRARY TABLE

The Practice of Surgery a Treatise on Surgery for the Use of Practitioners and Students By HENRY R WHARTON, M D Demonstrator of Surgery in the University of Pennsylvania Surgeon to the Presbyterian and the Children s Hospitals, and B FARQUHAR CURTIS M D, Professor of Clinical Surgery in the New York Post-Graduate Medical School and the Women's Medical School of the New York Infirmary Profusely illustrated London and Philadelphia J B. Lippincott Company 1898 Pp 1240 Price 25*s* net —We do not remember to have seen hitherto any American work which so closely approaches the ideal text book on surgery for students as does this book The advances in surgery of late years have so enlarged the bounds of the subject that it is every year increasingly difficult to compress into one volume all the surgical facts with which a student or practitioner should be acquainted We think that the authors may be congratulated on having produced a work which is readable and exact and in which the accounts of disease and injury are sufficiently detailed for the purpose for which the book is intended. A considerable degree of care has evidently been exercised in reducing to moderate dimensions descriptions of conditions and of treatment which would ordinarily have occupied many times the amount of space The 923 illustrations are drawn from many sources, but the majority are original and many of them are striking It is very characteristic of modern surgery that the first chapter of the book is devoted to an account of those bacteria which are of importance to the surgeon and though somewhat brief, it is probably sufficient It is obvious that 1200 pages of text must present many opportunities for discussion but we have been surprised to find very few points indeed on which we are decidedly at variance with the opinions of the authors who have evidently striven to present the general current views on debateable points rather than their own personal opinions The chapter on the Injuries and Diseases of the Eye has been written by Professor G E Schweinitz and it is fully as satisfactory as the rest of the book

On Varix, its Causes and Treatment, with especial reference to Thrombosis By WILLIAM H BENNETT, F R C S Eng, Surgeon to St George s Hospital and Joint Lecturer on Surgery in the Medical School; Member of the Court of Examiners of the Royal College of Surgeons of England, &c Reprinted from THE LANCET, Oct 15th, 1898, with the addition of Twelve Illustrations 8vo London, New York, and Bombay Longmans, Green, and Co 1898 Pp 63 Price 3*s* 6*d* —This is a reprint of an address which Mr Bennett delivered at the inaugural meeting of the Nottingham Medico-Chirurgical Society for the session 1898-99 It gives a very good account of a by no means unimportant subject and it is especially valuable as representing the personal opinions of the author on a diseased condition to which he has devoted much attention Mr Bennett considers that the causes of varicose veins may be divided into four classes, in many cases the varicose veins are congenital, and even when they are due to an obvious exciting cause, yet a congenital predisposition is extremely probable, in other cases obstruction of the blood current by pressure brings about the varicosity, in a third class are the cases which follow a strain, and in the remaining cases the cause is thrombosis The author gives several clinical histories which show strikingly the influence of severe strains in giving rise to varicose veins of the limbs As to the treatment, Mr Bennett lays great stress on the harm that may follow the use of ill fitting elastic stockings, he tells us that he has known grave thrombosis to result Operative treatment to be effective must include excision of a portion of the long saphenous vein a little above the knee so as to cut off the long column of blood in the valveless saphena The author insists on the fact that a "cure' in the ordinary meaning of the word can never be promised even in the cases most suitable for operation, though much discomfort may be relieved and conditions dangerous to the integrity of the limb and possibly to life may be removed

The Year book of Treatment for 1899 A Critical Review for Practitioners of Medicine and Surgery Illustrated. London, Paris New York, and Melbourne Cassell and Co, Limited Price 7*s* 6*d* —This, the fifteenth, annual volume of the Year book of Treatment is fully on a level with its predecessors, and in saying that we have said all that is necessary to those who have known earlier issues of this work The Year book of Treatment differs from most other year books of medicine and surgery in that it confines itself to treatment, and it is in treatment that most medical practitioners feel that they need some assistance in keeping up with the ever advancing tide of science The impressive list of contributors to this volume must serve to show that the articles fully represent the most recent additions to our knowledge Perhaps the most important section is that devoted to an account by Dr Burton Fanning of the Open air Treatment of Phthisis The copious indexes to authors and subjects add greatly to the usefulness of this valuable publication

Travaux de Neurologie Chirurgicale. Revue Trimestrielle, dirigée par le Docteur A. CHIPAULT. Paris: Vigot Frères. 29 Figures. 96 pp. Price 4 fr. January, 1899.—Dr. Chipault's journal, which has hitherto been published once a year, now makes its first appearance as a "quarterly." It consists entirely of original articles, several of them of great interest. 1. Experimental Researches on the Methods of Trephining in Prehistoric Times, by Professor Capitan. 2. On a Case of Local Lesion of the Rolandic Region (adhesions from meningitis), by Professor Raymond. The lesion gave rise to Jacksonian fits, but they continued after removal of the affected membranes. 3. A Case of Traumatic Abscess of the Right Temporo-sphenoidal Lobe, by Signor Roncali. One abscess was evacuated, but the patient did not improve and after death two large abscesses independent of the first were discovered, one in the right frontal lobe and the other in the middle lobe of the cerebellum. 4. A Case of Intradural Resection of the Posterior Cervical Nerve Roots for the Relief of Neuralgia in a Painful Stump, by MM. Monod and Chipault. 5. On Deviations of the Cord in Pott's Disease, by M. Cestan. 6, 7 and 8. Treatment of Perforating Ulcer by Nerve-Stretching, by MM. Duplay, Finet and Soulier. 9. On the Instruments required for Excision of the Sympathetic, by Professor Jonnesco. 10. A Case of Myxoma of the Superior Cervical Ganglion of the Sympathetic found at the operation of removal of the sympathetic for the relief of epilepsy in a melancholic patient, by M. Chipault.

The Microscope. By JABEZ HOGG, M.R.C.S. Eng., F.R.M.S. Fifteenth edition. London: George Routledge and Sons. 1899. Price 10*s.* 6*d.*—When a book has reached its fifteenth edition it is difficult to find anything to say about it which has not been said before. The first edition appeared so long ago as 1854, when, as Mr. Hogg remarks in the preface to the present edition, the microscope was seldom or never employed in the laboratory or in the medical schools. It is needless to say how different matters are nowadays. The present volume, though greatly enlarged from the former ones, does not pretend to deal with medical microscopy except in so far that it gives an account of one or two of the better-known pathogenic bacteria, such as the bacillus anthracis and the bacillus pestis. But as regards a large portion of the other subjects with which microscopy deals it is a mine of information. The book is very well printed and is fully and admirably illustrated.

Sajous' Annual and Analytical Cyclopædia of Practical Medicine. Vol II.: Bromide of Ethyl to Diphtheria. Philadelphia: The F. A. Davis Company. Price 5 dollars.—The second volume of this admirable work has made its appearance. We noticed Vol. I. in THE LANCET of May 28th, 1898. In the present volume will be found articles which are practically monographs by such authorities as Professor Adami of Montreal upon Cirrhosis of the Liver; by Professor Lépine of Lyons upon Diabetes; and by Dr. William Browning of Brooklyn upon Cerebral Hæmorrhage. There is also an admirable and exhaustive article upon Diphtheria by Dr. Northrup and Dr. Bovaird of New York. We have selected these articles not in any invidious sense but simply because they happened to be the most striking and to deal with the better known diseases, but the volume contains information upon nearly every conceivable medical and therapeutical subject within the alphabetical limits assigned to it. One omission, we have noted, occurs in the article on Calcium in which under "Therapeutics" there is no mention of the use of calcium chloride in hæmorrhages and various forms of urticaria as studied by Dr. Wright of Netley. The printing, binding, and illustrations of this volume are as admirable as those of the first.

JOURNALS.

Scottish Medical and Surgical Journal.—In the opening article of the February number Dr. J. J. Graham Brown discusses the Symptoms, Pathology, and Prognosis of Diabetes. Mr. Rutherford Morison contributes an Abstract of Clinical Lectures on Gall-stones. A gall-stone, he says, is more serious than a urinary calculus and the operation for the removal of the former is as safe as that for the excision of the latter. Dr. Francis D. Boyd describes two cases of Regurgitation at the Pulmonary Artery. The diagnostic features are the location of the point of differential maximum intensity in the second interspace to the left of the sternum; the conduction of the murmur down to the left border of the sternum; the area of audition of the murmur being wide downwards and to the left, very limited upwards or to the right; and the absence of any such characteristic alteration in the pulse as is found in aortic incompetence.

Edinburgh Medical Journal.—In the February number Dr. F. W. N. Haultain publishes a retrospect of a first series of 110 Abdominal Sections for Pelvo-abdominal Disease, with two deaths. Dr. J. H. Ferguson describes the occurrence of repeated Ectopic Pregnancy in the same patient. An article on the Bacteriology of Typhus Fever has been noticed already in THE LANCET of Feb. 11th (p. 390).

Dublin Journal of Medical Science.—In the February number Dr. Alfred Smith gives a summary of a second series of Abdominal Sections—100 cases with two deaths. Captain W. J. Buchanan, I.M.S., writes on Cerebro-spinal Fever in India. Dr. H. T. Bewley describes a case of Chyluria in which filariæ could not be found in the blood. Dr. Patrick Letters continues his paper on Preventable Disease in the Counties of Cork, Kerry, and Waterford. He mentions that in England only 58 persons died from typhus fever in 1895, but that in Ireland there were 129 deaths from this disease in 1896 and 121 in 1897.

Birmingham Medical Review.—The February number opens with a practical paper by Mr. W. J. McCardie on Nitrous Oxide and its Uses, with especial reference to the advantages of a mixture of nitrous oxide and oxygen. He has administered such a mixture several times most successfully for a period of a quarter of an hour and once for 24 minutes during a plastic operation on the vulva. The other original article is Dr. E. W. W. White's Middlemore Post-Graduate Lecture on Inflammations of the Conjunctiva.

Mercy and Truth.—In the February number Dr. A. R. Cook gives some notes of a journey of 750 miles in the neighbourhood of the lakes which supply the Nile. On the way he had many patients and did various operations.

Medical Chronicle.—The original articles in the January number are: (1) Observations upon the Pathology of Intracranial Suppuration of Otitic and Rhinitic Origin, by Mr. W. Milligan of the Manchester Ear Hospital, and (2) a continuation of a paper on Fractures and Dislocations of the Upper Extremity, by Mr. J. E. Platt, late resident surgical officer to the Manchester Royal Infirmary.

Monist.—A paper with the heading "Vitalism" in the January number is an examination from a metaphysician's point of view of Professor Japp's Presidential Address delivered before the Chemical Section of the British Association in 1898. The writer is Professor C. Lloyd Morgan of Bristol who takes up the position that "if by Vital Force we mean the noumenal Cause of the special modes of molecular motion that characterise protoplasm, its metaphysical validity may be acknowledged, so long as it is regarded as immanent in the dynamical system and not interpolated from without in a manner unknown throughout the rest of the wide realm of nature."

New Inventions

THE AUTOMEASURE (KEMPER SALOMON)

THE accompanying illustrations show an ingenious measuring device in its application to a medicine bottle Its construction is quite simple It consists (Fig 1) of a glass tube shaped somewhat like a funnel It is closed at the top by a tightly fitting cork containing a rubber valve kept in position by means of a spring On depressing the valve with the finger air may enter into the glass tube The capacity of the tube which we examined was one teaspoonful It is used in the following way The tube is fitted to the neck of the medicine bottle (Fig 2) by means of a cork collar On inverting the bottle the tube fills with the liquid On restoring the bottle to its original position the liquid remains in the glass tube It is then detached from the bottle and on depressing the valve with the finger exactly a teaspoonful of liquid is discharged It should be very useful for the purpose and is further an important introduction since it effects accuracy and uniformity of dosage It removes the objection of using teaspoons for the purpose which varying in size, give different doses It is very convenient to use and cleanly The specimens which we examined were submitted to us by Mr Richard Hilgers, Old Trinity House, 5, Water lane

FIG 1

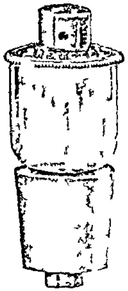

FIG 2

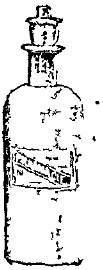

CLINICAL OZONE APPARATUS

THE employment of ozone as a gaseous antiseptic and in diluted form—that is, mixed with air for inhalation purposes—is now well known The convenient production of pure ozone is therefore of importance The device about to be described is an ingeniously designed generator which yields ozone with a comparatively mild current of electricity without being contaminated with irritating oxynitrogen compounds Its construction provides for the silent discharge of the current from the induction coil The inner glass tube is packed with small copper turnings while outside the tube is wound a spiral of copper wire upon which are strung beads of glass and steel alternately This tube gives a steady and uniform yield of ozone when the current is passed in the presence of air Tubes are thus constructed for inhalation and for the treatment of suppurating surfaces For the latter a kind of ozone pencil is used so that the action of the issuing ozonised air may be localised air being blown in at one end For the ozonisation of the air of a sick room or a ward a battery of these tubes is enclosed inside a cardboard barrel At one end a fan is placed which may be driven by a motor actuated by the same current The effect of this apparatus when working is very agreeable upon the air of the room giving it all the impression of freshness and removing disagreeable odours or that sense of stuffiness which characterises ill ventilated apartments With convenient forms of apparatus like the foregoing the application of ozone in disease, sickness and for other purposes should be given greater trial than has hitherto been the case The inventor, Mr Lamprey of Brockley, has devoted considerable time and energy to the design of ozone apparatus suitable particularly for the production of ozonised air for sick rooms or for the wards of the hospital He finds that ozonised air is extremely useful as a deodorant of fœtid discharges or evacuations.

“SUGAR-FREE WINES”

LAST week a *correspondent inquired* whether sugar free wines could be obtained and if so where We think the following results taken from the “Analytical Records from THE LANCET Laboratory” of the past few years may afford some generally useful information on this point as to spirits wines, and beers We may add that we have never found champagne, claret, or sherry to be absolutely free from sugar Several specimens examined, however, contained, as will be seen, an almost negligible quantity

	Sugar per cent
Champagne (sans sucre), Hertz and Collingwood 17 Billiter-street E C	0·2

THE NEED FOR MALE NURSES —At a meeting of the York Home for Nurses held at York on Feb 13th Mr W Draper made some remarks which are worthy of consideration He was of opinion he said that as far as possible male patients should be nursed by male nurses It was quite true that when men were laid on their backs with sickness they were under “petticoat government” and under existing conditions were glad enough to be so, but without *fear of contradiction* by far the majority of men he thought would much prefer to be nursed by well trained and capable nurses of their own sex Take for instance the sensitive delicate minded elderly gentleman who had of necessity perhaps to be suddenly handed over to the absolute care and dependency of a female nurse of 25 or 27 years Must it not be repulsive to him to say the least? Or take again the nervous bashful youth of from 15 to 20 years Was not the distress of his illness at all events at first much increased in consequence of the necessary offices of his watchful female attendant? Would ladies like to be nursed by men? In the army and navy the nursing was done by medical orderlies or sick bay men and well done *too* *Indeed he did not hesitate to* say that some nursing duties might be better performed by men than by women In these days there should be no difficulty in obtaining the services of plenty of temperate respectable and sufficiently educated young men who would be willing to go through a proper course of training in hospital and then to qualify themselves as efficient male nurses He trusted that the time was not far distant when every nursing institution of importance would have its branch for male nurses

THE LANCET.

LONDON: SATURDAY, FEBRUARY 25, 1899.

THE War Office authorities are, we think, to be heartily congratulated on having decided to establish a system of Army convalescent homes and the *Morning Post* is also to be congratulated on the result of its keen and strenuous advocacy in endeavouring to bring about such a reform. As far as the Army regulations are concerned the soldier has been hitherto regarded as sick or well; he was supposed to be in hospital if sick and to be fit for duty if well. There was no intermediate stage between the two and if sick or disabled soldiers were unlikely to become fit for the discharge of their military duties within a reasonable time they were supposed to be brought before a medical board and invalided. We do not mean to say that these regulations were always strictly carried out or acted upon, nor could they be. Practically speaking arrangements were commonly made for allowing soldiers either to proceed on sick furlough or for giving them light duty on discharge from hospital or during convalescence or sometimes no duty at all until their health was re-established. It was always, of course, within the power of medical officers to make recommendations to that effect which were almost invariably acted upon. Still, the system was not only attended with evils and occasionally disciplinary difficulties, but it was an unsatisfactory and, in a number of cases, very inadequate way of attaining the object in view. It is, indeed, impossible to lay down officially any arbitrary limits in regard to the recovery or otherwise of sick and injured soldiers because these would be so frequently opposed to nature's laws and methods. Everybody—most of all physicians and surgeons who have to deal with sick and injured patients—must recognise that after any long or acute, or even after any ordinary, case of illness recovery does not occur at once: there is almost always an interval during which the patient requires more or less time, together with some outdoor exercise altogether away from and outside the walls of a hospital, before his health is really re-established. In many cases, moreover, a more or less prolonged period of rest, good and careful dieting, and beneficial climatic effects may be absolutely necessary to ensure a patient's recovery. The provision of sanatoria at suitable stations will place these within the soldier's reach and may make all the difference between his return to duty on the one hand and his being invalided and altogether lost to the army on the other. What this loss amounts to in the aggregate we have no means of estimating but that it is large there can be no doubt. A system of sick furlough must obviously often be attended with many hardships and evils both to the sick soldier and to his relatives or friends—to the former from want of proper and skilled care and attention and the exposure to various temptations, and to his friends and relatives, when these are in needy circumstances, as they so frequently are, in subjecting them to a burden which not they, but the State, should be called upon to bear—to say nothing of the injurious effect which it exercises on the popularity of the Army. Many of our large civil hospitals have sanatoria or convalescent homes in connection with them; and so have continental armies. It cannot be too emphatically stated that the nation owes it as a duty to its sick and wounded soldiers to see that they are well cared for. It is nothing less than a national scandal that soldiers suffering from diseases and injuries attributable to their military service and of an intractable and possibly fatal character should not receive all reasonable consideration, instead of being weeded out of the army to swell the mortality-rate of the civil population.

We hail, then, this new policy of the State as regards the Army, in the establishment of convalescent homes for sick and disabled soldiers, as a much-needed reform and a very wise and humane step in the interest of all concerned. The convalescent soldier under the proposed scheme is to be drafted to barracks in stations where the situation and climate may appear most fitted to hasten his recovery. He is to be relieved of military duty and to be afforded facilities for the restoration of his lost health and strength. The experiment will be started in nine or 10 centres, to be selected according to their climatic recommendations, and it is hoped that it may be carried out during the ensuing summer. Barracks at Scarborough have been already utilised for the purpose and similar institutions will be soon started at Sandown, at Shorncliffe, and at Yarmouth. Existing buildings will be employed as far as possible and the other localities contemplated in the War Office scheme are Pembroke Dock, Tynemouth, Fleetwood, Ayr, and Aberdeen. It is to be hoped that as the scheme becomes further developed inland resorts, and some on elevated sites, will be selected, because seaside stations are not invariably the most suitable climates for patients who have suffered from tropical or subtropical diseases.

◆

IT is gratifying to find that in the United States of America the wholesome dread of undue developments of narrow specialism corresponds closely with the similar feeling which prevails in the United Kingdom. It is somewhat humbling to see the work of the medical profession broken up into bits as though the body were not one and indivisible or as if one portion of it could suffer in a splendid isolation from the rest. The illustrations of this evil are familiar to everyone and are sometimes conspicuous in regions where one would rather expect larger views of duty and disease to obtain. Thus, for instance, we find inspection of the mucous membrane of the larynx without examination of the chest; fanciful or slight diseases of the uterus or ovaries specially and gravely treated without reference to the general constitution of the patient; hæmorrhoids ligatured where malignant disease of the liver is beginning its fatal inroads on life; and all sorts of grave operations performed where there exist clear indications of the presence of fatal general conditions of which the local disease is but the climax To speak generally the tendency is to take a local view when everything depends on a broad and general view of the facts of the case The worst of it is that there is much in this specialisation of medical work which is agreeable to the patient and to the public The patient is gratified to have his disease duly labelled and localised and there is even sometimes satisfaction to him in the notion of having it dealt with surgically Moreover, there is comfort to him in the consideration that according to the specialists theory the disease is confined to one part, that it may possibly admit of simple excision or at any rate be carefully confined to its existing limits and treated by new fangled and merely local remedies The public, too, is taken by this view of specialism It accords strangely with its own crude notions of disease—notions which have been fed by ages of ignorance and quackery It is obvious that the belief of the public in an ever increasing specialisation of disease or rather of therapeutics is one of the strongest reasons for suspecting the truth of the whole doctrine and all the pretensions on which it thrives

We began by saying that the same wholesome dread of specialism which obtains largely in the profession here obtains equally in the best informed sections of the profession in the United States We have before us an address on the Dangers of Specialism in Medicine by Dr J BULKLEY, physician to the New York Skin and Cancer Hospital and consulting physician to the New York Hospital The address was delivered last year before the American Academy of Medicine by Dr BULKLEY in his capacity of President He is himself, it will be seen, a specialist but with a difference The Academy of Medicine over which he presides represents the educated medical opinion of the United States He expresses himself as thankful that owing to his not securing so early as he wished in life an appointment to a skin department he was thus driven to the study of general ailments We are naturally concerned therefore to ascertain his views as to the legitimate place for specialisation in medicine, the dangers which attach to it, and the way in which these dangers may best be averted He freely admits the uses of specialism and, indeed, that it is inevitable since the science and art of medicine in company with other sciences and arts have become so vast and extended that no one mind is capable of fully understanding every portion of it or of practising in every line in the best manner possible But withal he maintains that specialism is often cultivated and practised in a way which brings it and the whole science and art of medicine into discredit He enumerates several causes which contribute to this evil growth A fundamental evil lies in the desire of many young men to find short cuts to success and wealth by blazing out into sudden fame as specialists without any adequate general study of medicine in all its departments They are impressed with the success obtained by a few "ornaments of the profession who after long years of general study and practice have concentrated their mind on certain diseases or sections of practice and attained to eminence They are tempted to take up special work without laying the foundation in deep and general knowledge of medicine Sundry circumstances in the present organisation of the profession favour their vanity Amongst these Dr BULKLEY specifies the excessive m plication of cheap medical periodicals, with such a der for literary material that there is no difficulty in secu publication for all articles "however trashy" The m plication of medical societies is liable to a similar objec and favours the acceptance of papers and discussions likely to advance individual interests than scientific obj Medical colleges too, are apt to multiply special chairs w out having any thoroughly qualified persons to fill them

The remedy suggested by Dr BULKLEY—one in w all who have the interest of the profession at h will concur—is the more complete general education of specialist and the more thorough study of the whole r of medical knowledge as a basis for special practice specialist should grow out of the general practitioner should bring his ethical views of practice into harmony those which for generations have guided the conduc medical men The more a specialist isolates himself claims a right to act independently of the judgment of fellow practitioners the more is he to be regarded distrust by the profession and the public alike profession can best control the growth of the evil fo of specialism by recognising only those specialists wh reputation has developed legitimately They may be hel in their selection by Dr BULKLEY'S words "The specia should be a good physician *plus* the particular knowledg his specialty, or as someone has put it, he should h something of everything and everything of something"

◆

THE Government as we anticipated, have taken earliest opportunity to introduce their Bill to g facilities for the inter communication of the met politan water companies mains In introducing the Bill Tuesday last Mr CHAPLIN gave an outline of its provisio The metropolitan water companies under the direction of Local Government Board are within a certain time submit schemes for the construction of the works necess to carry out inter communication between their mains and is provided that in the case of an emergency the compan are to supply "at a reasonable cost, and to such extent a during such periods as the Board may direct, such water may be required for the need of any other metropoli water company and as may be available after satisfying t requirements of their own districts"—This provision is new departure in the treatment of the London water co panies Parliament has on previous occasions legislat concerning the charges which may be levied with rega to the sources from which water may be taken and wi regard to details of the supply The legislation has be partly by private Acts each of which as a rule affec one company only, and partly by public Acts which app to the whole of the metropolitan district Up to t present time, however, there has been no legislation givi power to the Local Government Board or to any other bo to interfere between one water company and another W do not see that the metropolitan companies can reasonab object to the Government measure on this point because the Bill which they themselves have already brought similar provisions are made It is not, however, on th account less worthy of remark that in giving the power direct interference between the different companies to the Local Government Board the Government is taking a perfectly new departure in legislative proposals for dealing with water companies.

Mr. CHAPLIN said that his Bill provided that the cost of construction should be borne by the several companies according to their respective water rentals and the terms upon which the water should be supplied were to be settled by agreement or by arbitration. To carry out the necessary work certain statutory impediments which at present exist are to be removed by the Bill. This provision, again, is on exactly the same lines as the Bill promoted by the metropolitan water companies. Mr. CHAPLIN explained further that the Local Government Board would be empowered to fix times within which schemes were to be submitted and the works constructed. With regard to the way in which the money is to be raised to carry out the work Mr. CHAPLIN explained that the Government has adopted the recommendation of Lord LLANDAFF'S Commission. This recommendation is contained in Section 37 of their first report and is as follows:—

"It was contended before us on behalf of the companies that inasmuch as the money raised by issuing the debenture stock could not yield revenue or profit to the companies, the sinking fund clauses, which are founded on the assumption that debenture capital is expended so as to produce revenue and profit, were not applicable. We think that there is force in this contention and that this debenture stock might be exempt from the obligations of the sinking fund clause."

Should this recommendation be adopted in its entirety it will, of course, be of great advantage to the water companies and a corresponding disadvantage to the London ratepayers and water consumers. Mr. CHAPLIN also explained that the Bill contained provisions under which, in case of purchase of the undertakings of the companies at any time within seven years of passing the Act, the companies would not be able to derive any increased allowance for advantages which they might obtain under this Bill.

We defer criticism of the details of the Bill, but we congratulate Mr. CHAPLIN on having so promptly brought forward a measure the principle of which ought in the public interest to be made effective by legislation as speedily as possible.

Annotations.

"Ne quid nimis."

THE SICK AND WOUNDED IN EGYPT.

ON Feb. 16th Mr. Wyndham replied to a question from Captain Norton in the House of Commons dealing with the alleged inadequate provision made in Egypt for the requirements of the sick and wounded returning from the late Nile campaign; and more especially with regard to *the failure of the War Office to comply* with the application of the medical service in June for a hospital ship, which was renewed in the following September by the general officer commanding in Egypt. The reply of the official representative of the War Office was, however, considered to be so unsatisfactory and inadequate that it called forth a communication from Colonel Lonsdale Hale in the *Times* of Feb. 21st, in which the action of the War Office is so adversely criticised and commented upon as to amount to a grave indictment against the Government. A question was again put by Captain Norton in the House of Commons to the Under Secretary for War on *Feb. 21st respecting* the unofficial application for a hospital ship by the general officer commanding and the principal medical officer of the army of occupation in Egypt in June last, and as to the nature and extent of the hospital accommodation and nursing staff provided at Cairo and Alexandria to meet the *necessarily increased* requirements caused by the engagements at Atbara and Omdurman. It appears from the reply of the Under Secretary for War that no steps were taken on the receipt of the intimation in June to fit out a hospital ship and to hold it in readiness to proceed to Egypt in anticipation of the expected renewed application, which came by telegram from the general officer commanding in Egypt *on* Sept. 14th—*too late then to* be acted upon. One thing is certain: no hospital ship was available at Alexandria although the medical regulations expressly provide that one is to be supplied under such circumstances, and no warning, unofficial or otherwise, was consequently necessary. Nevertheless, it was unofficially asked for in June by both the medical service and the general commanding, but no steps, as we now *learn, were taken to comply with their request. We can only* suppose that the explanation has to be sought for in the desire to "run the campaign in Egypt on the cheap" and that the Horse Guards' advisers of the War Office *may probably regard the* provision of a hospital ship for the Nile expeditionary force as a kind of "*fad*" of the medical service. That, *in addition to the* wounded, a large amount of sickness—of enteric fever especially—would follow on the conclusion of the campaign was about as certain as anything can be in war and just what all our previous experience in Egypt had taught us to expect. If the medical service or its authorised regulations had been to blame in this matter we should certainly have heard of it. We quite agree with an observation quoted in Colonel Lonsdale Hale's letter: "If £1000 of the money spent in booming the Sirdar in Egypt had been spent for the sick of the British division between 100 and 200 soldiers would have been alive now instead of lying in cemeteries in Egypt." We question, too, whether tents afford suitable accommodation for cases of sickness during September in a *climate like Egypt. We hoped that* this sort of parsimony had received its death-blow in the Crimea.

THE GOLDSMITHS' COMPANY'S GRANTS IN AID OF SCIENTIFIC RESEARCH.

THE Goldsmiths' Company has done much for scientific research and the thanks of the whole scientific world are due to its members for their generosity. A report has just been issued by the clerk of the Company explaining in a few words the advance which has been made in the laboratories of the Conjoint Board of the Royal Colleges of Physicians of London and Surgeons of England under the grant of £1000 made by the Company in 1894. The results obtained may be summed up thus: 1. Improvements have been made in the method of preparing diphtheria antitoxin which is now produced *more rapidly and of much greater* strength than was formerly possible. The more potent antitoxin is of great value in the treatment of diphtheria. A larger number of antitoxin units can be given in the same quantity of serum and thus there is far less immediate discomfort to the patient and its use is less often followed by rash and pains in the joints. It is much more convenient for transport and injection and, *lastly, larger doses* of antitoxin may be given because it is *contained in* a less quantity of serum. 2. The antitoxin value of serum is *now easily* ascertained and a permanent standard has been reached and kept preserved 3 Some knowledge of the structure of toxins and antitoxins has been acquired and inquiries into the action of the several constituent parts of the substances is still being carried on 4 Large quantities of strong antitoxin (about 13 000 doses) have been distributed to be used in the cases of poor people and hospital patients many of whose lives have thus been saved In consequence of this report the Company has made a further generous grant of £500 to the Conjoint Board Such open minded action cannot be too highly praised and the thanks not only of the medical profession but also of the public generally (although, perhaps, unconsciously given when members of families have recovered from diphtheria after use of the antitoxin) should be accorded to this great historical Company We further congratulate its members on having shown the courage of their opinion in spite of a band of unscrupulous agitators who, heedless of truth and reason, are prosecuting their cause with all the blind impetuosity of ignorance and misplaced sentimentality

INCREASE OF ALCOHOLISM IN FRANCE

DR JACQUET of the Hopital Saint Louis Paris is leading an active campaign in the hope of checking the ever increasing consumption of alcohol in France It appears if we may trust the vigorous denunciations made by Dr Jacquet that our French neighbours whom we have always considered a sober people in comparison with ourselves in reality consume a greater quantity of alcohol than do our countrymen This discrepancy may be explained by the fact that whereas English people drink to excess occasionally Frenchmen take less at a time but they drink more constantly There are fewer drunkards but there is much more alcohol consumed Dr Jacquet however protests that it is a mistake to believe that alcohol taken in small quantities but in frequently repeated doses is not injurious On the contrary these careful, sober people become alcoholic so gradually that they cannot perceive the injury which they have done to themselves till it is too late The man who is never intoxicated but who is constantly consuming small quantities of alcohol is in greater danger than the person who occasionally drinks to excess It is at the Hôpital St Louis that Dr Jacquet has been lecturing on this subject to audiences consisting of medical students trained nurses journalists, and other persons who take a serious interest in social questions That the question of alcoholism is becoming more and more urgent in France cannot be denied Other countries are improving but in France matters are going from bad to worse The consumption of pure alcohol at 100 hydrometer degrees is now equal to 2 000,000 hectolitres, and as the alcohol consumed is on an average at 40 hydrometer degrees this is equal to 5,000 000 hectolitres of ordinary alcohol The consumption of pure alcohol in France was estimated at one and a half litres per head of the population in 1850 In 1896 this average had increased to 4 19 litres But if to this the alcohol consumed in wines beers, and cider is added the average consumption of alcohol at 100 hydrometer degrees is equal to 14 litres per annum for every man woman and child in the country Apparently this figure is not reached by any other country In Belgium the consumption is only equal to 10 50 litres in Germany to 10 litres England comes next on the list and Sweden with only five litres comes last While in France the consumption has increased so also have the facilities for drinking In 1830 there were 280 000 drink shops, cafés, &c, and in 1896 these had increased to about 500 000 There is now one drink shop for every 30 adults of the population In the department of the Eure there is one drink shop for every 11 inhabitants—that is to say, for every three adults But these figures only deal with what is described as official alcoholism, there is a great deal of clandestine alcoholism which escapes the control of public statistics The most wonderful contrast is that set forth between France and Sweden In the latter country the annual consumption of alcohol was equal to 23 litres per head during the years 1830 to 1834, and in those three years 59 murders were committed During the three years from 1875 to 1878 only five litres per head per annum of alcohol was consumed and there were only 18 murders committed Such are some of the facts which Dr Jacquet is striving to impress upon the French public Perhaps, however, he somewhat spoils his case by going to extremes The strength of the French temperance movement is due to its moderation It does not fly in the teeth of the history of humanity It does not deny that pure wine is wholesome and even beneficent, but it insists on the necessity of purity Hence the French temperance advocate wages war against alcohol, especially manufactured alcohols—namely, alcohols which are not distilled from wine—but he allows the consumption of what are now termed hygienic drinks, that is to say, unsophisticated wine, beer, and cider Still even Dr Jacquet does not advocate absolute abstinence He urges that no one need take alcohol and that we gain in vigour and strength by abstaining from alcohol Wine beer and cider stimulate energy but should be taken in strict moderation, and it is, he maintains, absolutely false to say that wine gives strength Dr Jacquet exhibits lantern slide representations of persons suffering from alcoholism and shows specimens of human degeneration due to excess in drink As the general daily papers in Paris are beginning to notice these lectures they should produce a wholesome effect

MEDICAL OFFICERS OF HEALTH AND THEIR POWERS

MEDICAL officers of health rightly possess powers to examine and report upon milk and other food supplies but at the same time they must use the utmost reserve as regards suspicions which they may have concerning certain farms or shops until certain and reliable information has been obtained, otherwise purveyors of milk or other food stuffs may sustain great but unmerited harm A case of this kind was recently tried before Judge Ingham, at the Warwick County Court An action was brought by Mr Geo Cashmore, dairyman, of Leamington, to recover £50 9*s* 10*d* from Dr Samuel Browne, medical officer of health of Leamington, for circulating a certain report to the injury of the plaintiff s business It was alleged that early in June last four cases of typhoid fever occurred in Leamington and by a coincidence the families affected were all supplied with milk by the plaintiff Dr Browne went to the plaintiff s dairy to examine it and took a sample of milk and was overheard to instruct the sanitary inspector to ask Dr Bostock Hill, the public analyst to look out particularly for typhoid germs He did not inform the plaintiff of the result until he was asked and then admitted that no typhoid bacilli had been found Plaintiff then asked him what compensation he was to have for injury to his business and Dr Browne was stated to have replied that he had it in his power to ruin him as he had done in the case of another milkman It was also alleged that Dr Browne had told a gentleman whose daughter was suffering from typhoid fever that the milk was not fit for use and that he must throw it down the drain It was admitted however, that he afterwards informed the same gentleman that he could safely use the milk again and that he might write to the plaintiff to that effect Dr Browne denied that he had exceeded his official duty as a medical officer of health He simply advised the families affected not to use milk until it had been tested.

The plaintiff in angry terms demanded compensation and he referred him to the Health Committee of the Town Council. He then became abusive. Under these circumstances he reminded plaintiff of his powers as a medical officer and told him that under the Act he could prevent him from selling milk and that this would ruin him. The judge said he was bound to say that the defendant had only tried to do his duty as medical officer of health and the claim must therefore be dismissed. At the same time he regretted very much that, however insulting Cashmore might have been, Dr. Browne should to redress a private wrong have threatened him with the penalty which he could have inflicted only by virtue of his office as medical officer of health.

FOOD ADULTERATION.

MR. LONG's reply to a deputation of the Federation of Grocers' Associations last week encourages the hope that the Bill to be brought in by the Government will be both comprehensive and useful. We learn with satisfaction that dairy products are not to be treated separately but that all articles of consumption are to be included in a broad measure on the subject of general adulteration. Mr. Long assured the deputation that in any proposals to Parliament the Government would do nothing calculated to harass the great interests represented by the deputation or interfere with any properly conducted trade. Mr. Long evinced a singularly clear grasp of the position. He maintained that all that the public were entitled to ask for was that the articles should be sold for what they were and not for something else. If it could be shown that the law was not strong enough or wanted improvement in administration the country was entitled to have it. These are exactly the *sentiments which we have expressed again and again in these* columns. It is to be hoped that Parliament will accept a measure which will largely reduce, if not put an end altogether to, adulteration and fraud without hampering legitimate and honest dealing.

A UNIQUE CASE OF PSEUDO-HERMAPHRODITISM.

IN the *Centralblatt für Gynäkologie*, No. 5, 1899, Dr. Franz Neugebauer records a very interesting case of pseudohermaphroditism. The patient was a Jewess, 27 years old, who seven days previously had been confined at full term of a normally developed child. She was a well-developed, red-haired person of feminine appearance. The voice, the distribution of hair, and the breasts were all of the female type, and to outward appearances there was nothing at all suggesting the male sex. On examination of the genitalia the mons Veneris, the vulva, the labia, and the clitoris were normal. Situated about one centimetre behind the frænulum pudendi almost in the middle line of the perineum was an organ some 45 millimetres in length bearing a close resemblance to a penis. It was capable of becoming erect and swollen and of attaining a length of about 50 millimetres. It had all the appearances of a penis with a clearly distinguishable glans, incompletely covered by a prepuce. The skin covering it was wrinkled and folded like that of the penis of an old person, the folds, however, partially disappearing when erection occurred. The long axis was directed upwards, while the extremity was somewhat hooked and bent downwards like that of a hypospadiac penis. The meatus urinarius was represented by a small dimple, no trace of any opening being discernible. *Two corpora cavernosa were apparently felt,* of which the right but not the left could be traced to the ramus of the pubic arch. During erection the organ attained a size of about the thickness of the little finger, and this condition was accompanied by sexual excitement on the part of the patient. Nothing abnormal could be felt by the rectum and the labia majora were empty. A vaginal examination was not made, but there can be little doubt that the uterus and ovaries were present, seeing that the patient had just passed through a normal confinement. It was impossible to determine with certainty whether some of the folds of skin covering the abnormal body, especially at its base, did not represent a rudimentary scrotum. Unfortunately the patient was lost sight of owing to her having taken a situation as a nurse, and the operation for removal of the organ which had been recommended to her was not carried out. The question, therefore, as to whether the structure represented a rudimentary penis or a hypertrophied abnormally sensitive clitoris remained unsettled. Dr. Neugebauer has collected 37 cases of doubling of the external genitalia. Of these 28 had a double penis, three had a double vulva, and six had bisexual duplication; in none of the latter cases, however, has any post-mortem or histological examination been carried out. By most authorities the possibility of the occurrence of bisexual duplication of the external genitalia is denied, and the present case cannot be quoted as any proof of its occurrence seeing that the organ may well represent a hypertrophied clitoris. The case is, however, a unique one of its kind and it is to be regretted that Dr. Neugebauer was unable to carry out a further investigation of the interesting structure, such as might have enabled him to find some explanation of its extraordinary situation.

DEATH UNDER CHLOROFORM.

THE patient, a girl, aged two years, suffered from broncho-pneumonia and right-sided empyema. Although in a bad state there was nothing in her condition at the time of her admission into the Leicester Infirmary to fear immediate danger to life, but she grew worse and her breathing became much laboured. It was therefore determined to remove the pus by operation as aspiration had failed to relieve the condition. Chloroform was given by the assistant house surgeon, to whom we are indebted for the notes of the case. It was given by the "open method," small quantities being poured on lint and "freely diluted with air." The child was lying on her back and was never turned to the sound side, so that pus could not gravitate into and choke the left lung. Full surgical anæsthesia was successfully obtained and the operation was about to be commenced when the child ceased to breathe and died in spite of all restorative measures—artificial respiration, inhalation of oxygen, hypodermic injection of strychnine, and inhalation of nitrite of amyl. The administrator, who claimed an experience of 1000 administrations of anæsthetics, states that the child gave 10 or 12 "voluntary" gasping respirations before she succumbed. The extreme danger and difficulty of giving anæsthetics to patients suffering from empyema is well illustrated by this case. In general we prefer the use of the A.C.E. mixture when there is not too much bronchial irritation. In the present instance the case appears to have been *complicated* by the presence of broncho-pneumonia *so* that possibly the mixture would have failed. If the report which states that "full surgical anæsthesia" was obtained is to be taken literally we should join issue with the wisdom of such a practice as there can be little doubt that the "second degree" of Snow is the safest and is quite sufficiently deep for the proper performance of the operation. There is absolute analgesia and if the patient is restless he is never so much so as to interfere with the surgeon. Again, "artificial respiration" as performed by the Silvester system is a great source of danger to those apparently dead from chloroform when any fluid is in the lungs. Either the system of Marshall Hall *should* be carried out or the bronchus of the sound lung should be catheterised and inflated with care by means of bellows It would be of interest to learn whether any necropsy was performed (we may add parenthetically that in every case of a death under an anæsthetic a careful post mortem examination should be made) and if any pus was found in the bronchi of the left lung

A RUSSIAN SURGEON ON CLEANSING OF THE HANDS

DR CIRIKOW formulates his ideas regarding disinfection of the hands to the following effect in a recent number of *Vratch* 1 Cleansing of the hands by mechanical means Cutting the nails short, clearing the subungual spaces in the usual way, rubbing with a hard brush, green soap, and warm water during 10 minutes, all this does not give a satisfactory result From subungual matter and from the product obtained by scraping the palm and the interdigital regions it is still possible to cultivate colonies of bacteria 2 Placing the hands in a 2½ per cent solution of formol for a period of three minutes will not suffice for disinfection even though the measures just enumerated have been previously adopted 3 Neither a solution of permanganate of potash nor a 1 or 2 per cent solution of corrosive sublimate, whether hot or cold can be relied upon to yield better results than are to be obtained by milder antiseptic methods 4 The hands will beyond all doubt be disinfected if cleansed by mechanical means during three minutes, followed by brushing with a new brush in 95 per cent alcohol during three more When thus treated they will even remain aseptic after steeping in hot water during 12 minutes or after four or five minutes of perspiration Alcohol should never be used under 80 per cent and even at that degree the results are only semi satisfactory 5 Wood spirit at 92 per cent is very cheap and gives excellent results 6 The thread gloves used by Mikulicz have little value The experimenter s hands were first plunged into a liquid containing a little pyocyanic broth He then put on the gloves and after from three to five minutes numerous bacteria were found in the fluid with which they had become impregnated 7 Dr Cirikow is at present engaged in an examination of the gloves which have been proposed by Friedrich

"QUACKS AND ABORTION A CRITICAL AND ANALYTICAL INQUIRY'

A FEW weeks ago in one of our articles published under the heading of ' Quacks and Abortion A Critical and Analytical Inquiry' we predicted that owing to the prosecution of the Chrimes brothers the advertisements to which we called attention in detail would disappear for a time from more or less respectable papers at all events but would probably recur We confess that we did not expect to find them distributed broadcast again even in the more disreputable papers of London and the provinces so soon after the publicity given to the subject by the prosecution referred to and by our articles We have however, before us fully 100 newspapers published during one week of the present month in Great Britain in which occur the advertisements of persons of whose pretensions to procure abortion by means of drugs there can be no question while over 50 of these papers contain the advertisements of quacks with whom we dealt in our articles, publishing their names, their correspondence and the analysis of their wares Strange to relate in one paper, the *Orcadian* published at Kirkwall, we find the well known advertisement of the Chrimes brothers still appearing They are presumably expiating their misdeeds at Wormwood Scrubbs, previously to their removal to penal servitude while miserable women in Kirkwall and its neighbourhood are being incited by their specious promises to send postal orders to H B. Montrose of Ludgate circus where "the highest professional advice always free is promised with the removal of the "most obstinate obstructions' Let us hope that, whatever else the police may do or not do, at any rate they have officially notified to the Post Office the conviction of the Chrimes brothers and that the letters and money are promptly returned to their senders without the form of attempting to deliver them being gone through The Kirkwall editor is to be congratulated on the tranquil life which he lives undisturbed by the news of the outer world if not upon his insight into the character of his advertisements

THE DILATORY CHURCHWARDENS

SOME time ago the crypt of the church of St George-the Martyr, Southwark, was noticed to be full of fragments of burst coffins, bones, and other substances prejudicial to health After a good deal of discussion and perseverance on the part of Dr Waldo, the medical officer of health, a letter was written by the Home Office ordering the crypt to be cleared out The letter was dated August 11th 1898, but nothing more was heard of it until Jan 24th, 1899 when it was discovered in St George s Parish room The chairman of the vestry reported the matter to the vestry upon Feb 7th We see that the estimated cost of clearing out the crypt is £2000 and that a member of the vestry protested against this expenditure He is reported as saying that he did not believe that the clearing out was to be done on sanitary grounds, but that an attempt had been made to get a room added to the church at the expense of the ratepayers The beliefs of vestrymen and members of boards of guardians would, if collected, form a curious chapter in the history of human intellect

REPAIR OF THE RUPTURED UTERUS

IN the *Gazzetta degli Ospedali* of Feb 5th Dr Tullio Pozzan of Vicenza relates a successful case of repair of rupture of the uterus The patient, who lived in the country and was 41 years of age, had had seven natural labours all with head presentations Two years after the last she again became pregnant the confinement being expected in the middle of August, 1898 Pains of no great intensity commenced on the evening of Aug 14th and continued all through the night The membranes broke at 10 A M next day The midwife stated that the dilatation of the os was nearly complete and that she could touch the fontanelles The pains then became frequent and strong but the presenting part did not advance and the symptoms of rupture occurred suddenly Dr Pozzan saw the patient at 4 A M on Aug 16th, about 15 hours after the accident The fœtus could be easily felt in the peritoneal cavity covered only by the extremely thin abdominal walls The os was soft and dilateable, no portion of the fœtus presented The woman having been removed to the General Hospital of Vicenza Dr Pozzan at 7 A M made an incision in the linea alba six inches long from the umbilicus to near the symphysis, whereby he was able easily to remove the fœtus and placenta The laceration of the uterus was in the lower segment of the anterior wall, irregularly transverse in direction extending towards the left and involving the broad ligament, the upper margin was well in sight, but the lower margin was hidden behind the bladder Clots meconium, &c, were wiped up with napkins wrung out of boiling water The lower margin was then brought into view by pushing it up with the finger in the cervix and the muscular layers of the two edges were stitched together with silk The visceral peritoneum was then united with another line of stitches and the abdominal parietes were closed without drainage The operation lasted 50

in the

pounds and was 20 inches in length, the diameters of the head were normal. After the operation the patient's highest recorded temperature was 38·6° C. (101·4° F.). She left her bed on Sept. 1st and was discharged recovered on Sept. 10th —namely 25 days after the operation. Two months subsequently Dr. Pozzan found her to be in excellent health. The uterus had subsided to its normal dimensions but was anteflexed as a result of the cicatrisation anteriorly. He says that Merz in 1894 was able to collect histories of 39 laparotomies after rupture of the uterus; of which 18 were successful. To this number must be added a case which occurred in the practice of Dr. Paolo Rossi of Vicenza in June, 1891. The patient was 40 years of age and had had six normal labours. Rupture of the uterus occurred in the seventh and laparotomy without suturing the uterus was performed at her own home. She was able to leave her bed after 29 days and was then perfectly recovered.

THE INTERNATIONAL CONGRESS OF GYNÆCOLOGY AND OBSTETRICS.

THE third session of the International Congress of Gynæcology and Obstetrics will be held at Amsterdam from August 8th to 12th, 1899. The questions arranged for discussions (at which already several prominent medical men of different nationalities have promised to be present) are as follows: 1. The Surgical Treatment of Fibro-myoma. 2. The Relative Value of Antisepsis and Improved Technic for the Actual Results in Gynæcological Surgery. 3. The Influence of Posture on the Form and Dimensions of the Pelvis. 4. The Indication for Cæsarean Section compared with that for Symphysiotomy, Craniotomy, and Premature Induction of Labour. The official languages are English, French, German, and Italian, and the reports with their translations in the official languages will be sent to all the members a month before the opening of the Congress. As regards private communications preference will be given to those bearing upon the above-mentioned leading questions. Time will also be allowed sufficient for any demonstrations. The subscription for membership is one guinea. Subscription forms and further particulars may be obtained from the honorary secretary for Great Britain and Ireland, Dr. Arthur Giles, 37, Queen Anne-street, London, W.

"EUTHANASIA."

THE letter which we print this week from Mr. W. G. Burnie in reply to one from "Euthanasia," calls to mind a question which from time to time must suggest itself to every medical man. Such cases as our correspondent described occur only too frequently and the doubt as to how far we are justified in pushing anodynes and anæsthetics naturally causes us considerable anxiety. In reply to his queries we believe, however, it would have been perfectly justifiable for him to have used morphia hypodermically and patients are frequently kept under chloroform cautiously administered for hours to mitigate the sufferings caused by convulsions—e.g., those of tetanus. Medical men must frequently ask themselves whether it would not be more humane in certain cases to purposely administer an overdose of morphia or of an anæsthetic. We refer, of course, to those patients suffering from a malady which is perfectly incurable, which will undoubtedly cause death within a very short period, and in which as long as the patient survives intense agony will be experienced. No one can deny "that it would be the kindest thing to do," but the physician's duty is to attempt to save life, never to destroy it. It is wonderful how much pain can be relieved without danger to life by the suitable administration of anodynes, and we consider that a practitioner is perfectly justified in pushing such treatment to an extreme degree, if that is the only way of affording freedom from acute suffering. With morphia, in the majority of cases, there is but little risk; in cases of extreme cardiac weakness it may certainly be given; the only doubtful cases are those in which there is advanced renal disease, and then it is for the physician to decide which is likely to be of more harm to the patient, the prolonged agony or the morphia; or whether the administration of some other anodyne should be tried, and if that fails then whether chloroform inhalation should be given. If the risks be explained to the friends we are of opinion that even should death result the medical man has done the best he can for his patient. But this is a very different matter from purposely giving a larger dose than is necessary. The various suggestions which have been made as to consultations for discussing the question of painlessly shortening the existence of a fellow-being are hardly to be taken seriously. If such a mode of treatment were suggested it would be so open to abuse by the unscrupulous persons who are unfortunately to be found in every rank of life that the medical profession would never countenance it.

PETROLEUM LEGISLATION.

WE are evidently a long way from obtaining a definite pronouncement from the Government on the vexed question of altering by statute the flash-point of petroleum oil. Mr. Jesse Collings stated to a deputation last week that the matter was receiving close and serious consideration. The members of the deputation who spoke and who represented the Federation of Grocers' Associations urged that legislation should be directed to the construction of the lamp rather than to the adoption of a much higher minimum flash-point of the oil. One remarkable statement was worthy of note. A gentleman stated that "the vendors who provided oil for the 10,000,000 lamps in use every night and day in Great Britain wish to enlist the sympathy of the department in opposing any legislation which suggested the raising of the flash point, the evidence before the committee being entirely in favour of no alteration." The subject of future legislation in this matter is beset with peculiar and great difficulty and it is a pity that this difficulty is not diminished by the sensational statements as to lamp accidents which appear so frequently in the daily press.

THE COLOUR OF PRIMITIVE MAN.

IN the February issue of *Knowledge* Professor Arthur Thomson writes the first instalment of what promises to be a series of very interesting articles on the Treatment and Utilisation of Anthropological Data. The first article deals with the question of colour—a question which has attracted considerable attention in the fields of physical anthropology. Whilst on the one hand it has been maintained that primitive man was fair in complexion, on the other hand it has been maintained that he was of a dark tint. "It is not necessary for us," says Professor Thomson, "to accept the extreme position. ...... A middle course is open as suggested by Dr. A. R. Wallace who advances the view that primitive man was probably of a Mongoloid stock and that his subsequent modification into white and brown and black varieties was due to his migrations into geographical areas where he was subject to the influence of varied conditions of climates." The writer, however, does not commit himself to the acceptance of such opinion but remarking that the theory is suggestive draws attention to associated details of importance in studying the question. Among them

> "Temperature may be mentioned, diurnal as well as nocturnal. The moisture of the atmosphere. The nature of the soil. The diet. The manner of life, whether dwellers in dense forest or jungle—where, for example, the natives are screened from the sun's rays, or dwellers on the hills and

plains where they are most exposed to light and alternations of temperature. ...... Freckles, which, curiously enough, occur most frequently on those with hair of a pronounced red colour, do not differ in any respect from the pigmented skins of the darker races except in regard to their colour and their circumscribed appearance. In persons of dark complexion there is, in addition to the red, brown, and yellow pigments, probably a very slight admixture of the black pigment. This may be present in sufficient quantity to impart a blackness in the hair but not abundant enough to destroy the fairness of the skin, though in exceptional situations its presence may be very evident." It is curious to note that "when the skin of a white man is grafted on to a negro the grafted patch assumes the normal tint of the individual, and, *vice versa*, when black skin is grafted on to white the pigment disappears"

The article, which is illustrated with photo-micrographs, deserves careful perusal.

THE LATE PROFESSOR KANTHACK.

WE publish in another column a letter dealing with the question of a memorial to the late Professor Kanthack. The form of the proposed memorial is, we think, very admirable, for it is intended to provide for the widow of the deceased during her lifetime and after her death to apply the capital sum to some permanent memorial of him who was one of our most brilliant pathologists. All who knew him should subscribe according to their ability. He was known to many personally, to more perhaps by his work, and there should be no difficulty in collecting an adequate sum for the objects set forth in our correspondence columns.

THE ARTHRITIS OF CEREBRO-SPINAL MENINGITIS.

DR. OSLER has contributed an important paper to the *Boston Medical and Surgical Journal* of Dec. 29th, 1898, on this subject. Arthritis is a very inconstant symptom. An old writer, North, in his valuable "Treatise on a Malignant Epidemic commonly called Spotted Fever" (New York, 1811) mentions "swelling like rheumatism of the joints." In the recent outbreak in Boston arthritis occurred in six out 111 cases. Dr. Osler relates two cases. In one the onset was abrupt and accompanied by chill. There were marked fever, stiffness of the neck, splenic enlargement, delirium, and unconsciousness from which the patient could not be roused. The arthritis was the most prominent symptom. The right wrist, the elbows, and knees were red and swollen. The condition of the joints suggested pyæmia, but the deep coma and rigidity of the neck cerebro-spinal fever. There was consolidation of the lower part of the right lung which appeared to be pneumonic, but while meningeal symptoms in ordinary pneumonia are not uncommon they are rarely associated with stiffness of the neck, and arthritis is excessively rare. Lumbar puncture gave a turbid fluid containing lymph and the diplococcus intracellularis. Half an ounce of pus obtained from the right knee showed the diplococcus and the blood also contained it. This is the first case in which during life the organism has been isolated from the blood and joints. The necropsy revealed purulent cerebro-spinal meningitis. In the second case the illness began with pain and redness and swelling of the right ankle, then the left ankle and right hip were affected. The diagnosis was doubtful, but typhoid fever was suspected. Pain in the back on the sixth day and retraction of the neck (without rigidity) on the seventh day aroused suspicion. The joint symptoms subsided completely. On the twelfth day the legs were limp and paraplegic and there was anæsthesia as high as the umbilicus surmounted by a band of hyperæsthesia. There were no reflexes to be obtained from the legs. Lumbar puncture gave exit to two drachms of pus containing suspicious looking diplococci. The lower part of the cord was exposed and thick pus was drained away. A small catheter was passed under the dura mater and the membranes were irrigated with normal saline solution. Much pus escaped. The patient was improved in health at the time of the report. The infectious arthritides while common in some fevers are very rare in others. The general view has been that the arthritis of cerebro spinal fever is a secondary effect of the meningitis; the separation of the organism from the blood and joints in the first case shows that it may be the direct effect of a widespread diplococcus septicæmia.

THE MILROY LECTURES: AN INTERESTING EXHIBIT.

AT the close of his first lecture Dr. Poore exhibited an interesting series of rabbits which had been buried in wire cages for a year at different depths and under different conditions. The results of these experiments will be dealt with in an appendix. The specimens will be again shown at the close of the lectures on Tuesday and Thursday next to anyone interested in the subject.

PRIVATE MUNIFICENCE AND MEDICAL RESEARCH.

IT will be remembered that some little time ago Mr. Balfour made an eloquent appeal for the richer endowment of medical research. In commenting on the speech of Mr. Balfour[1] we remarked that we hoped it was a foreshadowing of a Government grant in aid of such research. Our hope has so far not been realised and so private generosity has come forward. We learn that Sir Frederick Wills has forwarded to the treasurer of Guy's Hospital a cheque for £5000 to be used for the benefit of the medical school. It is perhaps only fitting that an institution founded by private charity should continue to benefit by the munificence of a private benefactor, but we think it quite time for the State, which has in the past (and very probably will in the near future repeat its action) laid rude hands upon the moneys of pious founders, to do something for the carrying on of that research upon the results of which the health and happiness not only of the living but of those yet unborn may depend. However this may be medicine and science can and do unite in offering very hearty thanks to Sir Frederick Wills

"TIGER NUTS."

A NOT infrequent and very troublesome form of rectal obstruction in children arises from the practice of eating what are known as "tiger nuts." These nuts are of a somewhat flattened conical shape, from a quarter to half an inch long and inclosed in a dry, brown, inseparable skin marked with transverse ridges. Being small they are apt to be taken in considerable quantity and being hard they are commonly swallowed in a crushed but unmasticated state. The natural result as it is revealed to the practitioner who is called in a few days after this injurious repast is a peculiarly painful impaction of the rectum. The finger passed within the anus finds itself in what feels like a mass of small coal. Defecation is a misery. Enemata are at the outset of treatment nearly useless. The finger and the spoon are equally painful and inadequate, and the only effectual method of evacuation with which we are acquainted is to administer chloroform and carefully unload the rectum with an ordinary ovum forceps. This process ought to be followed up by bland disinfectant enemata used alternately with others of olive or linseed oil. Sometimes the removal of the nut-fragments is followed by a species of mucous diarrhœa which is unpleasantly suggestive of the mischief which they are capable of causing in th

---

reason why a multitude of irritant foreign bodies should always pass in safety to the alimentary terminus. Another question related to this subject is that of responsibility for the cause of the illness. The case is emphatically one for prevention and this duty cannot safely be evaded by parents, teachers, and any others who are entrusted with the care of children. We are also of opinion that a caution should be issued by the sanitary authorities to keepers of sweet-shops and to corn-merchants condemning the sale of these mischievous nuts as human food.

THE MECHANISM OF ELECTRO-THERAPEUTICS.

OUR Rome correspondent writes: "On May 4th Como will celebrate the hundredth anniversary of the day on which her great citizen Volta invented the pile which goes by his name. The occasion will be utilised for the holding of an International Exhibition of Electricity, the success of which the Government is coöperating with the city and province to ensure. Several of the Ministers (those of Public Instruction, Public Works, Commerce, and Agriculture as well as of the Home Department) have announced their intention not only of being present but of awarding medals to those of the exhibitors who have been most successful in contributing to the practical uses of electricity. A section will be devoted to its various medical applications—a field in which Italy has a highly honourable record. The catalogue alone, with its descriptive letterpress, will in this department have much to interest the medical profession, while the electro-therapeutic appliances in which the latest developments are to be represented will furnish a series of object-lessons from which the intelligent visitor cannot fail to profit. The season, moreover, the 'tempo Maggese,' is that at which the lake and its surrounding scenery are at their best, and those of your readers who contemplate a holiday at that time or who may be lingering in the Italian lake-country on their return from the winter cities farther south might do worse than give a few days to Como and its celebration of the 'Centenario di Volta.'"

THE LIVERPOOL LOCK HOSPITAL.

THERE is probably no disease which is so widely spread or so far-reaching in its effects as syphilis and those who are most acquainted with its ravages are those who feel most earnestly the importance of treating it energetically, for every case which occurs is a menace to the health of the community in which it exists. Cases of syphilis and of the other venereal diseases are treated in the out-patient department of most of the general hospitals, but at the present time in the London general hospitals there are only 57 beds available for female patients suffering from venereal disease—a number utterly inadequate for the satisfactory treatment of these serious diseases. There are only six lock hospitals in the British Isles and an attempt is being made to close one of the most useful of these hospitals. Mr. F. W. Lowndes has shown in the January number of the *Liverpool Medico-Chirurgical Journal* how valuable lock hospitals and lock wards are in the treatment of venereal affections and how the patients are in numerous cases benefited morally as well as physically. He describes all the lock hospitals in Great Britain and Ireland, and especially the Liverpool Lock Hospital, with which he has been associated for 23 years. All lock hospitals have great difficulty in obtaining pecuniary support and this fact must tend to curtail their operations. The Liverpool Lock Hospital is under the committee of the Royal Infirmary, but the great additional expense is not counterbalanced by an additional increase of income and therefore it has been proposed to close the hospital. This would be a most regrettable step, for the benefit of in-patient treatment in the severer cases of venereal disease cannot be gainsaid, and although it is true that the majority of those treated are suffering from the consequences of their own vicious conduct, yet the patients include many married women and children who are afflicted from these diseases through no fault of their own; and, moreover, the fact that the patient suffers from any disease because of his or her own misconduct can never justify a refusal of treatment, for there is no law of proportion between the degree of immorality and the severity of the disease. We earnestly hope that the committee of the Liverpool Royal Infirmary will see their way to continue and even to extend the benefits afforded by the Liverpool Lock Hospital.

SANITATION AND THE DEATH-RATE.

WE quote the following extract from the report of the Chicago Department of Health for 1898. From a scientific point of view such comparisons are useful, but they also serve the important object of educating the public in the results of medical science as applied to public health.

"During the Victorian jubilee, 1897, one of the addresses presented was on the subject of sanitary improvements during the preceding 60 years and their effect on the saving of life. The speaker—the Lord Mayor of London—cited Macaulay's comparison between the London mortality of 1844 and that of 1684 which showed that the death-rate of the latter year, "not a sickly one," was between 43 and 44 per 1000, or one in every 23. He then went on to show that in 1897 the London death-rate was 14·9 per 1000, despite the enormous increase in the population. During the 10 years from 1838 to 1847 the mean annual death-rate for England and Wales was 22·16 per 1000, while that of the 10 years from 1881 to 1890 was 19·1 per 1000. 'This implies that 77,000 out of an estimated population of 29,000,000 were kept alive in each year of the latter period who would have died in each year of the former,' and this saving of life is attributed to sanitary improvements during the period. Here in Chicago there may be shown a still more remarkable saving of life. Thus during *the decade 1845–54 the annual* death-rate was 43·3 per 1000; during the decade just closed (1889–98) the annual death-rate has been 16·3 per 1000, and during the last five years of this decade the death-rate has been 14·4 per 1000, or a fraction less than the London death-rate of 1897. This implies that upwards of 46,500 out of an average annual population of 1,611,235 were kept alive in each year of the last five years who would have died in each year of the period between 1845 and 1854. These figures are further sustained by a study of the ages at death of 10,208 who died in 1872 (the records prior to 1872 were destroyed in the Great Fire), of 12,141 who died in 1882, of 27,259 who died in 1892, and of 11,655 who died during the first six months of 1898. The average age at death in 1872 was 15 years and two months; in 1882 it was 19 years and six months; in 1892 it was 23 years and four months; and for the first six months of 1898 it was 29 years and seven months. This implies an increasing duration of life in Chicago of nearly 50 per cent. during the last quarter of a century."

MEDICAL GLEANINGS FROM ROMAN EGYPT.

IT is probable that no archæological literary discovery of the expiring century will in future be so celebrated as the rescue from the sands of the Egyptian Fayoum of more than 10,000 complete and fragmentary papyri by the explorers acting under the auspices of the "Græco-Roman Branch of the Egyptian Exploration Fund," a society which at its commencement owed much to the late Sir Erasmus Wilson. A selection from some 1400 documents, the greater part of which are at Oxford and the minority at the Ghizeh Museum, has been made by Messrs. Grenfell and Hunt who have carefully edited about 150 of them and published them with a commentary in a volume entitled "The Oxyrhynchus Papyri; Part I., with Eight Facsimile Plates." First in importance is the now famous portion of a "Logia" or collection of "Sayings of Our Lord." There are also pieces by Sappho, Thucydides, Plato, and other classical writers The first papyrus of medical interest is No. 39, which is from the military archives of Oxyrhynchus, and is the certificate for the release from army service of one Tryphon because of defective eyesight It reads thus "Copy of release, dated and signed in the twelfth year of Tiberius Claudius Cæsar Release from service was granted by G Vergilius Capito, prefect of Upper and Lower Egypt, to Tryphon son of Dionysius, weaver, suffering from cataract and shortness of sight, of the metropolis of Oxyrhynchus Examination was made at Alexandria' Another papyrus gives an account of a lawsuit relative to the identity and the custody of an infant who had been placed with a baby farmer, Papyrus No 51 is the report of a medical officer upon a case of suicide and is dated A D 173 A similar document is to be found in the large collection of Greek papyri in the Berlin Museum The present one is as follows "To Claudianus, strategus, from Dionysius, son of Apollodorus, son of Dionysius of Oxyrhynchus, public physician I was to day instructed by you through Heraclides, your assistant, to inspect the body of a man who had been found hanged, named Hierax, and to report to you my opinion upon it I therefore inspected the body in the presence of Heraclides at the house of Epagathus in the Broad street quarter and found it hanged by a noose, which fact I accordingly report'

THE trustees of the Reid Trust for the Education of Women have decided to offer a scholarship at the London School of Medicine for Women in memory of their co trustee, Miss Bostock of Penmaen, Glamorganshire lately deceased The value of the scholarship will be £60 a year, tenable for from two to four years, and will be awarded on the result of the preliminary scientific examination of the University of London The Bostock scholar must read for the London medical degree Further particulars may be obtained from the honorary secretary of the Reid Trust, Bedford College York place W

THE Royal Agricultural Society of England, with the object directly of assisting dairy farmers in meeting the present requirements of sanitary authorities and indirectly of preventing the spread of tuberculosis through dairy products, has issued a small leaflet full of wise suggestions to all whom it may concern Copies of this leaflet may be obtained free of charge on application to the secretary of the society at 13, Hanover square, London, W.

WE regret to announce the death of Dr Arkle from pneumonia after only three days illness Deceased had just resigned the vice deanship at Charing Cross Hospital Medical School where also he was Lecturer on Biology and Joint Lecturer on Practical Medicine

---

THE explanatory memorandum of the Army Estimates has been issued There is an increase of £10 000 for the medical establishment, coinciding with provision for 18 additional officers and 150 men for the Royal Army Medical Corps

---

SIR JOHN STIRLING MAXWELL, BART, M P, has consented to preside at a festival dinner in aid of the funds of University College Hospital to be held at the Whitehall Rooms Hôtel Métropole on Thursday, June 15th

---

DR J M ROSS until now medical officer of the county of Dumfries, has been appointed county medical officer of health for Wiltshire,

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE fifty second sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Feb 14th. The Chairman (Lord Llandaff) and all the other Commissioners were present The witnesses examined were Mr Frank Henry Wybroo, Mr Mather Wilson Hervey, respectively secretary and chief engineer to the West Middlesex Waterworks Company, and Mr Frederick Tendron, chairman of the Grand Junction Waterworks Company

A number of statements were put in referring to the works of the West Middlesex Company These included a description of the engines and of the pumps, a table showing the freehold and leasehold land used by the company, and statistics extending in some cases as far back as 1851 referring to the amount of water supplied, to the population, and to the number of houses supplied Constant supply was first given to 326 houses in the year 1873 This number amounted to 0 7 of the entire percentage of houses supplied At the end of last year the number of houses under constant supply numbered 74,692—89 5 of the total number of supplies given The daily amount of water supplied per head has increased somewhat irregularly In the year 1852 it amounted to 27 5 gallons per head daily; in 1862 to 30 7, in 1872 it was rather less—28 9, in 1882, 25 4, in 1892, 31 1 In the year 1898 it was 34 9 The tables put in give full details with regard to the pumping capacity and to the length of the mains An estimate was given of the future capital expenditure of the company—that is the amount which it was supposed will have to be spent in order to carry on the undertakings up to the year 1937 Tables were also given showing the gross and net profits and other financial details

Mr WYBROO in answer to the CHAIRMAN explained that the net profits fell in the year 1895 because of the expenditure which it was necessary to make as a result of the effects of the frost There was a diminution in the net profits in the year 1894 which was due to a "rebate to the water consumers Discussion arose as to the meaning of the word 'rebate" and as to the propriety of its use

In answer to Mr MELLOR the witness said that every consumer in the company's district had his water rents reduced This was a statutory reduction because the company were able to pay their shareholders 10 per cent

Mr BALFOUR BROWNE preferred the expression "reduction of charges

Mr PEMBER thought 'rebate a good word

In answer to Mr MELLOR the witness said that a rebate of five per cent was allowed upon all water rents from Midsummer, 1887 It was not allowed before that time because back dividends had not been paid

In answer to the CHAIRMAN the witness said that it was not true that the poorer classes paid more than the richer in the districts supplied by the West Middlesex Company. On the contrary, the poor paid less than the rich

The CHAIRMAN said that Mr Gomme of the London County Council had pointed out that the expenditure of the company went up considerably after the year 1887—that is to say, as soon as the company had paid its back dividends and could therefore divide amongst themselves only 10 per cent by way of dividend The witness said that the annual amounts put down for maintenance in the tables which had been put in were correct The expenditure for the years 1886 and 1887 was due to the fact that a greater amount was spent on filter beds Money was spent at that time because it was necessary, the work was not done before because it was not required In the years 1887 and 1888 new filter beds were constructed at a cost of £21,000 The payment of that sum was spread over two years

In answer to Mr. DE BOCK PORTER the witness said that between the years 1878 and 1887 there was no exceptional expenditure

In answer to the CHAIRMAN the witness said that there were no new works during those years and the extra works which were done were paid for out of revenue

The CHAIRMAN examined the witness with regard to the revision of the capital of the company which took place in the year 1852 The company claimed that at that time their capital amounted to £830,000

The Chairman asked how it was that Parliament lopped off the difference between £506,697 and £830,000. The witness explained that although some of the capital of the company was raised at par and the shares were fully paid up some other capital was raised at no less than 70 per cent. discount. At one time the authorised capital was £400,000, but to get £400,000 the company issued 8300 pound shares for which they only got £396,000. Parliament allowed them to fix as their capital the actual amount of money which had been received for the shares.

Mr. Pember read extracts from the Act of 1852 which he remarked "put it as clean as a whistle." He also inserted interpolations of his own and the Chairman remarked that when counsel interposed observations of his own in reading the text for the first time it was extremely difficult to follow. Briefly the fact is that the amount allowed by Parliament was the sum which had been actually subscribed by the shareholders plus the amount which they had spent in the works and part of which was paid out of their dividends. (During the early struggles of this and other companies the adventurers instead of paying a dividend often used their profits for the maintenance or extension of their works. See history of the Lambeth Company, The Lancet, March 13th, 1897, p. 757.)

In answer to the Chairman the witness said that the Vestry of Paddington had applied to a magistrate in the year 1823 to fix the charge for water supplied for municipal purposes. At that time the price charged by the company was 9*d.* per 1000 gallons but the magistrate altered the rate *to 8½d.*

In answer to Sir John Dorington the witness said that he could not tell on what grounds a magistrate in such a case gave his decision.

Mr. Claude Baggallay said that he had had to argue a case just before Christmas and that he was unable to say what the guiding principle in the decision was.

Mr. Pember suggested that the magistrate acted as an arbitrator and not as a lawyer, but Mr. Baggallay said that the magistrate gave *reasons* for his decision, but that it was very difficult to apprehend them and he could not attempt to explain them. Mr. Lewis asked whether the decision of one magistrate was respected by another magistrate. Mr. Baggallay said that he was unable to answer that question.

With regard to the effect of the decision of the House of Lords in the case of Dobbs *versus* the Grand Junction Company the witness said that the company revised their charges after this decision. In some cases the charges were lowered, in some cases they were raised. In a great many cases the company was charging on a sum less than the rateable value of the property. The result of the revision of the water rents of the company was favourable to the company.

The Chairman suggested that they were obliged to reduce some of their rates but screwed up all the others, but the witness pointed out that they had not raised them as much as they had a right to do for it happened that when Torrens's Act was passed and rateable value was made the standard on which water rents were charged there was another revision which resulted in a further increase to their revenue. The decision of the action in the case of Dobbs and the Act of Torrens were both favourable to the revenues of the West Middlesex Company.

With regard to the question of meters the witness said that the *cost of supplying meters* to the whole of London would amount to about £1,500,000 and the cost of *fixing* them would amount to £1,000,000 more if they were placed outside the houses. If they were placed inside the houses the cost would be less but special legislation would be necessary. It would also be necessary that a scale of charges should be fixed to produce incomes equal to the present ones received by the companies and in addition a meter rent would have to be charged.

The Chairman thought that there was nothing absolutely sacred about the present net income of the companies, but Mr. Pember expressed the hope that the 10 per cent. was in the canon.

Mr. Balfour Browne referred in some detail to clauses relating to the fixation of the capital of the company in the year 1852 and pointed out that the words of the Act were that capital should be taken as £506,300 divided into 8300 shares of £61 *each* and that the nominal value of the existing shares of the company was to be reduced from £100 to £61 *each.*

Mr. Hervey, in answer to the Chairman, *explained* the tables which had been put in with regard to the statistics of the expected increase in the population supplied by the West Middlesex Company. He said that according to Lord Balfour's estimate the company would in the year 1937 require 10,000,000 gallons a day more than at present. This water they hoped to get from the Thames and the cost of doing so and of making the alterations requisite for its distribution would, he thought, amount to £1,250,000. They would require a new covered reservoir which would cost about £50,000, new filter beds costing £150,000, new mains costing £300,000, and engines, boilers, and buildings amounting to £200,000.

The Chairman referred to a proposal which had been made to divide the undertakings between the county of London and the county of Middlesex so that each of these districts might have an independent supply. The witness replied that that would be a very difficult thing to do and would entail a large expense the amount of which it would not be easy to estimate. Several of the reservoirs belonging to the company which are situated within the county of London supply districts outside the county of London; and, again, reservoirs situated outside the county of *London* supply districts inside that county. All the mains are laid down so as to give a supply most conveniently under the existing conditions; if those conditions were altered it would necessitate a double series of mains in a very large number of places. The arrangements for the purification of the water are situated in the county of Surrey; all the water passes to *Hammersmith whence it is pumped to the districts supplied.* Roughly speaking, about a quarter of the water is supplied in the county of Middlesex and the other three-quarters in the county of London. If a complete severance of the arrangements for the purification and distribution of the water were made the subsidence reservoirs would have to be divided. At present the water passes to the pumping stations at Hammersmith in a common tunnel and a *fresh* tunnel would have to be made. The pumping station at Hampton is in the county of Surrey; if a complete severance of the supplies were made there would be a difficulty *as to the* mains from Hampton to Barnes. *Filter-beds* would *also* have to be separated and divided between the county of Middlesex and the county of London. The whole of the distributing mains would have *to be* remodelled *so as to* pump direct to the county of Middlesex without interfering with the mains supplying the county of London.

In answer to Major-General Scott the witness said that it would be extremely difficult to divide the filter-beds and the engines between two authorities assuming that the severance took place on the lines suggested by Sir Alexander Binnie. At the present time the filtered water is collected *into one* shaft from which it is passed through a tunnel under the Thames to Hammersmith.

The Chairman questioned the witness as *to the* experience he had had with regard to the deposit of *mud* in the reservoirs. The witness said that 18 months ago they had cleaned out a reservoir for the first time for a period of 30 years. This reservoir which was *situated at Barnes* received water pumped directly from the river. The accumulation of 30 years amounted to an average *of 8·42 of* liquid mud; of this a large proportion, certainly 50 per cent., was water.

In answer to the Chairman the witness said that in flood time the water was much more foul and contained more solid matter in suspension than when the river was *not in flood.*

In answer to Mr. Mellor the witness said that in the year 1866 they cleaned out *four acres* of filter beds which had been constructed in the year 1852. The interior of the beds contained a certain amount of *coloured* matter but it was found that practically the *whole of* the *matter* in suspension in the water had been arrested at or *near* the surface of the bed. During the process of *filtration a film is formed* on the surface of the filter. This *film* is visible to the naked eye and does not require a microscope *or any* other scientific apparatus to detect it. During the *summer* time when the water is good the film *on a* filter *bed* which has been at work for a couple of months does *not* amount to more than the eighth of an inch in thickness. In the winter when the water contains more suspended *matter the film* is formed more quickly but it has the same appearance.

In answer to Major-General Scott the witness said that before the reservoirs were made at Barn *Elms* the company had to deal with water which was more or less *muddy.* This was passed through subsidence reservoirs before filtration.

When the water was more or less muddy it was found that after filtration the colour was not so good as the filtrate of water which was not originally muddy. Flood water was always coloured and the colour could not be eliminated.

Major-General SCOTT suggested that the quality was not as good when they had to deal with flood water as when they had to deal with water in its best condition. The witness admitted that he did not see how it could be so good because the river water at its best was practically chalk water. Under the Staines Reservoirs Scheme water derived from that source would be treated by subsidence before it was filtered. The arrangements of the company were such that it could not possibly be used otherwise. The witness thought that it was desirable that flood water should always pass through subsiding reservoirs. If the water were not allowed to subside a larger number of filters would be necessary.

In answer to Mr. MELLOR the witness said that the first sign of the choking of a filter was that the water passed through the sand less rapidly; therefore if the water were allowed still to flow on to the filter bed at the same rate the level of the water on the bed would rise. A filter-bed may remain in an efficient condition without becoming choked for a week, a month, or two months, according to the quality of the water filtered. It was the duty of a man to watch the filter night and day.

In answer to the CHAIRMAN the witness said that in the case of flood water the water after filtration was always more coloured in the winter than in the summer time. The difference could be detected in an ordinary bath.

SIR GEORGE BRUCE said: "If you notice it in a bath you would not notice it in a tumbler."

In answer to Mr. MELLOR the witness said that the coloured water did not necessarily imply that the water was of a bad quality and he gave the Glasgow water as an instance.

Mr. PEMBER suggested that it was very like the difference between diamonds of different water. It made a great difference to the value per carat, but nobody but an expert would know it and Mr. BALFOUR BROWNE agreed that the value was very much affected.

In answer to Major-General SCOTT the witness said that he did not attach much importance to the possession of a recording apparatus to show the rate of filtration. He was aware that such arrangements were in general use in Berlin, but the manner in which water was to flow on to the filter bed must be controlled by the individual in charge and the only use of the arrangement was that it gave a record of what was actually being done

In answer to Mr. MELLOR the witness said that there was not the least objection to the apparatus.

Mr. FREDERICK TENDRON said that he had been chairman of the Grand Junction Waterworks Company for two years. He did not think that the people of London would gain by buying the water companies' undertakings at any rate for the present. With regard to the company in which he was concerned he would say, Leave the undertakings in the hands of the company and they will obtain their 10 per cent. maximum and possibly also their back dividends sooner than any public body purchasing the undertakings could arrive at the same financial point, therefore the consumer would benefit more rapidly if things were left as they are than if the company were transferred to a purchaser.

The fifty-third sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Feb. 20th. The Chairman (Lord Llandaff) and all the other Commissioners were present. The sitting was occupied in hearing the evidence of Mr. Frederick Tendron and Mr. Harry Wilkins (secretary to the Lambeth Waterworks Company). A large number of documents were put in during the sitting. The appendix to the shorthand notes which contains these consists of no less than 60 pages Amongst these papers there is a statement with regard to the present condition of the Grand Junction Waterworks Company and a number of tables giving particulars with regard to the Stock Exchange value of the stocks of the company at different periods and as to various financial and other details. There is a statement containing particulars with regard to the estimated future capital expenditure which will be necessary and statements with regard to the statutory limits of the supply of the company. These tables cannot be reproduced in THE LANCET

Mr. TENDRON at the beginning of the sitting made a correction with regard to some evidence which he had given concerning back dividends and the examination which immediately followed had reference to the increase of population which would probably take place within the Grand Junction Company's area of supply. The witness said that, taking 22·3 per cent. as the decennial increase of the population within the company's area, in the year 1937 the population would amount to 920,800 and he proceeded to give an estimate of the amount which, in his opinion, it would be necessary for the company to expend in order to supply this population with an average quantity of 35 gallons per head per day and in providing that a quantity of 42·7 gallons per head daily should be supplied occasionally. The witness estimated that the amount which the company would have to spend would only be £1,063,420, but this was on the assumption that they would be allowed to obtain water from the Thames and that the flow of the river should, if necessary, be reduced to 100,000,000 gallons per day.

Mr. HARRY WILKINS stated that the company which he served did not wish to sell their business and that he was present at the interview which took place between Sir Arthur Arnold on behalf of the London County Council and various representatives of the metropolitan water companies. It may be remembered that Sir Arthur Arnold at the nineteenth and twentieth sittings of the Commission gave his impressions as to the result of this interview which were to the effect that the representatives of the water companies would be willing to sell their businesses. The witness said that on behalf of the Lambeth Company he did not at that interview either agree that the company would be willing to sell their undertaking nor did he give his assent to any particular terms on which purchase might be effected. At the present time the company do not assent to the arbitration clauses suggested by the London County Council. Mr. Banbury's scheme[1] would, in his opinion, require considerable modification before it could be accepted by the water companies.

In answer to Mr. DE BOCK PORTER the witness said that he could not say how long it would be before the company would be likely to reduce their water rents. The witness thought that the companies ought not to be prevented from pumping dry the wells which belonged to other people, and practically he gave it as his opinion that the companies ought not to be placed under any rigid control with regard to their arrangements as to their future supplies. He gave it as his opinion that the provisions of the sinking fund clause were atrocious.

---

[1] Mr Banbury's scheme for the purchase of the Metropolitan Water Company's undertakings was given on the thirtieth sitting of the Royal Commission, which was held on July 18th, 1898. (See THE LANCET, July 23rd, 1898)

THE PLYMOUTH POLICE SURGEON.—At a recent meeting of the Plymouth Town Council the Watch Committee reported that as the result of correspondence passed between Mr. Wolferstan, police surgeon, and the town clerk with regard to the duties and office of the police surgeon they had resolved that Mr Wolferstan be requested to resign the office at the termination of the current financial year. After a considerable discussion the council negatived the minute of the Watch Committee by 30 votes to 11. Mr. Wolferstan who has been police surgeon in Plymouth for 25 years is to be congratulated upon this result.

VACCINATION IN BARTON REGIS (EXETER).—At the meeting of the Barton Regis Board of Guardians held on Feb. 17th the clerk stated that the particulars of the return respecting the vaccination of children from Jan. 1st to June 30th, 1898, in the vaccination districts of Clifton, St. Philip and Jacob, Ashley, Westbury, Stapleton, Winterbourne, and St. George were as follows: number of births returned 1570, successfully vaccinated 619, insusceptible 3, dead not vaccinated 137, and "conscientious objections" 58. The number of these births which on Jan. 31st, 1898, remained unentered in the vaccination register was as follows: postponed by medical certificate 84, removed to districts of which the vaccination officer has been apprised 107, and removed to places unknown 30. The number of these cases remaining on Jan. 31st, 1899, neither duly entered in vaccination register nor temporarily accounted for in the report book was 532

Obituary.

WILLIAM RUTHERFORD, M.D. EDIN., F.R.S.,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF EDINBURGH.

THE medical profession, not only in Scotland or the United Kingdom, but in every country where a school of medicine exists, will share with us our deep regret at the death of Professor William Rutherford, Professor of Physiology in the University of Edinburgh, which occurred on Tuesday last, Feb. 21st, at his residence, 14, Douglas-crescent, Edinburgh.

Professor Rutherford was born at Ancrum in Roxburghshire just 60 years ago and was educated first at one of those local grammar schools of which Scotland is so justly proud and afterwards at the University of Edinburgh which he was later to adorn with his great gifts of teaching and investigation. He graduated in medicine in 1863, obtaining the gold medal for his thesis, and after filling the usual resident appointments became assistant demonstrator of anatomy at Surgeons' Hall, Edinburgh, his chief being Professor (now Sir John) Struthers. He then went on a tour of the great continental medical schools, which were at that time—that is to say, in 1864—far better equipped scientifically than the British schools. He visited and studied at Berlin, Vienna, and Paris, and when he returned to Edinburgh a year later was already marked out as a rising physiologist. In 1865 the late Dr. Hughes Bennett, who had himself studied deeply in the French and German schools of medicine and who was at that time Professor of the Institutes of Medicine in the University of Edinburgh, appointed Rutherford as his assistant. Here he showed himself so thoroughly competent and advanced a physiologist that it came—at any rate, to his Scotch contemporaries—as but little surprise that in 1869, when only 30 years of age, he should be appointed Professor of Physiology in King's College, London. In 1871 he became Fullerian Professor of Physiology in the Royal Institution of London, and in 1874 returned to his old University of Edinburgh as Professor of Physiology.

The following estimate of Professor Rutherford's work in the chair with which his name will be for ever associated is from the pen of Professor Sims Woodhead, not his least distinguished pupil:—

"Those Edinburgh men who first knew Professor Rutherford in 1874 will scarcely be able to realise Edinburgh University without its late Professor of "The Institutes of Medicine." Those of us who attended his first series of lectures will remember the impression which was made, not so much in the introductory lecture perhaps as when he came to deal with the real work of the session. We should as soon have thought of going without our morning bath or our breakfast as of missing a single minute of Rutherford's lecture or of the catechism which so frequently preceded it. At first we were struck by the thoroughness and patience with which he drilled into us the most elementary facts, but any feeling thus generated was rapidly lost in our admiration of the never-failing success of his experiments, which we soon came to see was the result not only of a wide and accurate knowledge of his subject but of an enormous expenditure of time, ingenuity, and labour. There can be no doubt that the influence exerted by Rutherford in moulding the minds and careers of the men who came within its sphere was due not so much actually to what he taught (though that was always most carefully brought up to date) but to the fact that we were led to look upon his lectures and demonstrations as the manifest outcome of an enormous amount of labour and careful preparation. Whatever Professor Rutherford's position may be in future as an original experimentalist his influence in that direction can never for a moment compare with the influence which he has had indirectly as a teacher, and had he not made a single contribution of his own to physiological science his name in future must rank amongst those of the great teachers of whom Edinburgh is so justly proud. With all this, however, Rutherford was always an ardent investigator, and such time as was not devoted to the preparation of his lectures and demonstrations or to music was given to investigation. I well remember the awe with which I was inspired when I was allowed to go and help in a very small way by counting the drops of bile or by watching the respiration of animals with which Rutherford, assisted by the late Dr. Vignal, was carrying on his experiments on cholagogues and the secretion of bile. Early and late during our summer sessions were these men at work, and we students recognised in Rutherford a man of great physical energy, of strong intellectual power, and of untiring interest in the study and teaching of physiology. This general impression it was that explains the enthusiasm with which his assistants—of whom I remember Stirling, De Burgh Birch, Berry Haycraft, Anderson Stuart, Mc Cormack, Ashdown, Alexander, and Carlier—entered into the work of the department.

"Professor Rutherford with all his little peculiarities and mannerisms—in fact, perhaps partly because of them—was a great favourite with the students. He was a good musician and an old secretary of the University Musical Society; and the present writer—a secretary of later date—who had the pleasure of serving with him on the committee of that society, recalls that it was during the time of Rutherford's membership that this society was at its best. Many old Edinburgh Musical Society men will have the pleasantest recollections of his appearances in the music class-room where, in the intervals of choral singing conducted by Sir Herbert Oakley or the late Mr. G. O. Sinclair, or between the organ solos of Professor Oakley, he would join some of the groups of students and discuss with them the knotty points connected with the work of the society, or encourage a nervous musical lad. Who will ever forget the roar of applause which always greeted his appearance at one of the old K. C's., as slowly mounting the platform he would advance to the piano, and with chest thrown forward, head well back, eyelids half closed, after a few preliminary chords would announce that he would sing "a little thing of his own"? Then with wonderful voice and a dashing accompaniment he would give "The Warrior's Pledge," a stirring song of which both words and music were his own.

"Of his many kind and generous actions to students in difficulties probably no man will ever know, but many a man has gone to him when he has been in difficulty, and often, where more than advice was required, has come away not empty-handed; while several men who could now ill be spared from our ranks owe it to Professor Rutherford's kindliness and generosity that they have been able to complete their medical studies. Two instances at least have come to the personal knowledge of the present writer. During the period of his nervous breakdown the students who had known Professor Rutherford before this illness came on could not understand the change which appeared to have taken place in him, but throughout it all they remained loyal to their old teacher and no one rejoiced more heartily than they on his restoration to health. Whoever may be appointed to succeed him must necessarily be a good man, for there are many able physiologists from amongst whom his successor will be selected, but whoever he may be, and whatever his qualifications, he can never exactly fill the place of Rutherford, at any rate in the estimation of his old pupils. He was a great landmark in the history of the University—a great teacher, a man who appeared to keep in sympathy with his pupils from his very earnestness in work and who, had he been less shy and had his mannerisms been fewer, might not have attracted the student as, considering the nature of his work, it was his good fortune to do. I have gone to him on all kinds of errands—to ask him to sing, to ask him to give prizes, to ask him to subscribe to the athletic club funds, to the Musical Society, to the Union, to come out to the University games, or to specially patronise some athletic function—and never once have I come away empty-handed or without feeling that his contribution was given or his presence promised because he took a real interest, not only in the work, but in the healthy amusements of the students. Some men exert one kind of influence for good, others another, but it will be easily seen that whatever weakness or foibles Rutherford may have had his interest in and desire for the welfare of his students were both genuine and deep."

To Dr. Sims Woodhead's words there remains little for us to add. From the time that Rutherford went back to Edinburgh as Professor of Physiology his life was his work, and the earnestness with which he threw himself into it was the common knowledge of all, as it was the subject of common admiration. He was elected a Fellow of the Royal Society in 1876, having then been for 16

years a Fellow of the Royal Society of Edinburgh. His published works comprise a treatise entitled "The Outlines of Practical Histology," which was published in 1877; "The Action of Drugs on the Secretion of Bile," a book recording the results of his own elaborate investigations which was published in 1879; certain introductory addresses to his classes summarising the scope of modern physiology; and contributions to the Transactions of the Royal Society and of the Royal Society of Edinburgh, to the *Journal of Anatomy and Physiology*, and to our columns, where his excellent "Lectures on Experimental Physiology" first appeared with full illustrations.

Professor Rutherford fell a victim to influenza. Some fortnight ago he was suffering from this insidious epidemic, but he had rallied and the sad issue was not in the least expected. On Monday evening, however, he experienced a relapse which terminated fatally.

CHARLES BADER, M.R.C.S.ENG., L.S.A.,

CONSULTING OPHTHALMIC SURGEON TO GUY'S HOSPITAL.

THE death of Mr. Charles Bader was announced in our columns last week. The regretted event took place on Monday, Feb. 13th, at his country house at Stoke Ferry, Norfolk, where he had lately passed most of his time.

Charles Bader was educated in his native land, Germany, and came to London in 1861 to be assistant ophthalmic surgeon to Mr. A. Poland who with Mr. J. F. France then had charge of the eye wards of Guy's Hospital. He was elected full ophthalmic surgeon to the hospital in 1873 but filled the post for nine years only, having left the hospital 17 years before his death which occurred at the age of 72. During his 20 years of service to Guy's Hospital he did excellent work for the special branch to which he was attached, raising it from a very small department to a position as high as that enjoyed by any special department of any metropolitan hospital. He was a man of great energy, a brilliant operator, and also most original in his methods, so that it is not surprising that for many years he had a very large private practice.

Mr. Bader was a man of many interests outside his profession, a fact which accounts to some extent for the pleasure which so many of his patients took in his society. He was a good athlete, and could box and fence better than most men. Since his retirement from the active staff of Guy's Hospital, particularly of late years, he was much interested in the raising of stock, and bred large quantities of sheep and horses on his Norfolk property at Stoke Ferry where he died.

WILLIAM THOMSON CRABBE, F.R.C.S.EDIN.

BY the death of Mr. William Thomson Crabbe, which occurred on Feb 13th, Birmingham has lost one of her best-known medical men. Mr. Crabbe was educated at Edinburgh, taking the L.R.C.P. and L.M. in 1865 and the F.R.C.S. in 1872. He practised for some time near Edinburgh, but finally made up his mind to devote himself entirely to medical mission work. He commenced this first of all at Aberdeen, but in 1876 accepted an offer to go to Birmingham as the head of the newly-founded Medical Mission in that city. There his work was so successful that soon it became necessary to provide further accommodation. In the spring of 1896 Mr Crabbe's health began to fail and he took a six months' holiday, visiting Egypt and the Holy Land—a proceeding which greatly benefited his condition. He continued his work until December, 1898, when he was taken suddenly ill. He underwent an operation with the result of obtaining relief, but he gradually got weaker and died on Feb. 13th. He leaves a widow and three sons, two of whom are members of the medical profession.

CHARLES ARTHUR DIXON, M.R.C.S.ENG., L.R.C.P. LOND.

BY the death of Mr Charles A. Dixon on Feb. 6th at the age of 30 years the medical profession in Leeds has sustained a severe loss, his career from early student days down to the time of his enforced retirement from active work having been one of great promise. His good work at the hospital under the late Mr. McGill gave him an early reputation in medical circles and in later years he built up a large practice. He was one of the first anæsthetists appointed to the Leeds Infirmary and discharged the anxious duties of that responsible office in a manner which won for him the respect and admiration of those with whom he worked. Unfortunately, however, an attack of influenza followed by pleurisy cut short his onward progress. After passing through a prolonged illness it was thought best for him to seek a milder climate and he undertook a voyage to the Cape, intending to settle there. On the outward journey, however, his strength began to fail and on landing symptoms developed themselves which compelled him to obtain advice, which was to the effect that he ought to return home at once. A week later found him again on board; a very rough voyage hastened the end and he was landed at Southampton in a dying condition. His relations met him and there was little more than time to say farewell, for two days later he died. Those who knew Charles Dixon's sterling honest upright character feel that they have lost a friend whose memory will remain.

SAMUEL LEONARD CRANE, M.D. PENN., M.R.C.S. ENG., C.M.G.

THE death is announced on Jan. 25th of Dr. Samuel Leonard Crane. The deceased was born in 1830, graduated as M.D. of the University of Pennsylvania in 1850, and became a Member of the Royal College of Surgeons of England in 1855. He was Surgeon-General of Trinidad from 1871 to 1893, superintendent medical officer for Jamaica from 1893, and a member of the Legislative Council from 1894. In 1888 he was made a Companion of St. Michael and St. George.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Karl Schönlein, of the Naples Zoological Station. He was born in 1858 and studied in Halle. He was afterwards assistant to Professor Fick in Würzburg and for a couple of years acted as Professor of Physiology in the University of Santiago, Chili. Since 1892 he had been in charge of one of the divisions of the Naples Zoological Station. His published papers dealt principally with the physiology of the nervous and muscular systems.—Dr. Joseph Finger, Emeritus Professor of Medicine in Lemberg, at the age of 80 years.—Dr. Denis Monier, Professor of Biological Chemistry in the University of Geneva.—Dr. Wolfhügel, Professor of Hygiene and Bacteriology in the University of Göttingen.—Dr. Thomas, formerly Clinical Professor of Medicine in the Rheims Medical School.—Dr. Leon Fluymers, Assistant in the University of Liége.—Dr. Joseph Ritter von Maschka, formerly Professor of Forensic Medicine in the German University of Prague, a post which he held from 1858 to 1891. He was exceedingly popular both with students and with the laity and was at various times elected to important and honourable posts by his professional and professorial colleagues. He was in his seventy-ninth year.

LITERARY INTELLIGENCE.—Mr. H. K. Lewis will publish immediately the Lumleian Lectures, "On the Principles which Govern Treatment in Diseases and Disorders of the Heart," by Sir R. Douglas Powell, Bart., M.D. Lond. The same publisher has also in the press a new work by Mr. J. W. Taylor, F.R.C.S. Eng., on "Extra-Uterine Pregnancy," also a work by Dr. Maro Tuchmann "On the Exploration of the Urethra and Bladder." Both of these works will be fully illustrated.

VACCINATION LITERATURE.—At the meeting of the Cirencester Board of Guardians held on Feb. 15th it was stated that an answer had been received from the Local Government Board in reply to a letter from the guardians asking whether they had power to incur the expense of purchasing and distributing literature in favour of vaccination. The Local Government Board wrote that, assuming this literature to consist of pamphlets and leaflets and to be issued by some responsible authority on the subject, the Board would have no objection to the guardians incurring reasonable expense in obtaining the same and distributing it in the union. The guardians decided to send a copy of the letter to Dr Bond, the medical officer of the union and honorary secretary of the Jenner Society, asking him to send the necessary pamphlets for distribution.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Persistence of Enteric Fever in the Swinton and Pendlebury Urban District and on the Sanitary Circumstances and Administration of the District; by Dr. THEODORE THOMSON.[1]—At a time when much attention is being given to the causation of endemic typhoid fever, accounts such as Dr. Thomson gives of the circumstances of the Swinton and Pendlebury district, where for 10 years past there has been a sustained attack-rate and a correspondingly high mortality from this disease, will be read with exceptional interest. This district lies some four miles to the north-west of Manchester and it had a population at the last census of 21,637. The inhabitants are for the most part colliers, weavers, and cotton-spinners, and nearly all the houses in the district are inhabited by persons of the working class. The district stands upon drift—principally glacial sand—overlying the coal measures. Mortality statistics given by Dr. Thomson for the period 1888-1897 show that as a whole the death-rate from all causes in Swinton and Pendlebury is much the same as that of England and Wales. The zymotic death-rate in the former, however, is materially higher, while the death-rate from enteric fever plus continued fever is more than double the "fever" rate in the 33 great towns and two and a half times that of England and Wales. In dealing with attacks of enteric fever Dr. Thomson contrasts the annual attack-rate from enteric fever (as shown by notification returns) in Swinton and Pendlebury with corresponding rates in certain towns during the five years 1893-97. In the former case the annual attack-rate per 1000 of population during the period 1890-1897 was no less than 2·13. In the latter case the statistics are, so far as we are aware, new, and they have so high a value as standards of comparison that we quote Dr. Thomson's table in full.

Towns.	Annual attack-rates per 1000 from enteric fever during the five years 1893-97.	Towns.	Annual attack-rates per 1000 from enteric fever during the five years 1893-97.

In Swinton and Pendlebury the water-supply is the same as that of Manchester. It is obtained from Thirlmere, and may be regarded as free from suspicion of conveying enteric fever infection. This is merely a repetition of the experience of numerous other localities where notwithstanding water supply of undoubted purity typhoid fever is endemic. The sanitary circumstances with which the prevalence of enteric fever is associated in this district are such as freely conduce to soil pollution—"unpaved and badly paved yards, allowing refuse, both liquid and solid, to pollute the ground; defective house and yard drains, bringing about a like result; and, above all, large privy middens containing the accumulated excreta of months, much of the more liquid part of which soaks into and fouls the neighbouring soil. In addition to the fouling of the soil thus brought about by these middens, pollution of the ground surface takes place each time they are cleansed, by reason of their contents being cast upon passages and streets and left there pending the removal of these matters by the nightsoil cart." These defects, as well as many others enumerated by Dr. Thomson, show that the district council can hardly be excused from charges of indifference to the public health of their district. Administration by the sanitary department appears to have been lax, although latterly there has been some improvement. But evidently satisfactory progress cannot be expected until a larger staff has been provided. The local authority contracts with Manchester and with Salford for hospital isolation of infectious cases, but to what extent their enteric fever cases are usually isolated in hospital does not seem to have been determined. Dr. Thomson lays stress upon the association of enteric fever with neighbourhoods inhabited by the working classes and the poorer classes. To what extent poverty and dirt, apart from any special association with polluted soil, faulty drainage, accumulation of excrement near dwellings, and the like, conduce to enteric fever infection, and what is their share in endemic enteric fever, are interesting questions. The report shows clearly how great the influence of soil pollution has been. Dr. Thomson's observations on this subject bring home to the reader the need there is for investigations of the kind which he has pursued in Swinton and Pendlebury in a large number of districts where enteric fever is endemic with a view to determining what are the essential factors which go to make up a condition of soil which is capable of harbouring the typhoid bacillus from year to year. Comprehensive inquiry in this matter, supplemented by laboratory investigations, might, we think, be instituted with great advantage by the central public health department of the country.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Carlisle Urban District.—Mr. William Brown, the medical officer of health of this district, furnishes some interesting information in his current annual report as to dealing with tuberculosis in Carlisle. An experienced veterinary surgeon has been appointed who examines all the dairy cattle in the district once every three weeks and he also makes a careful examination of all cows newly received into the Carlisle cow-sheds. Since this appointment six cases of tubercle of the udder and six cases of mammitis have been detected. The tuberculin test is, too, being looked upon with favour in Carlisle and cows found to have tuberculosis of the udder are either slaughtered or removed out of the district where apparently they may still yield milk which eventually reaches Carlisle. Mr. Brown tells us that the statistics of the Carlisle public slaughter-house have brought out the fact that cows of the shorthorn breed are very prone to general tuberculosis and he exhorts dairymen to select some other breed less liable to this disease. He recommends the Scotch Galloway or the cross-bred blue-grey kinds. Mr. Brown thinks that phthisis should be notifiable and he is of opinion that medical men would willingly supply the necessary information.

Thingoe Rural District.—The Thingoe Board of Guardians, which is nearly identical with the district council, passed at their last meeting in 1898 a resolution expressing their opinion that great danger has arisen by virtue of the conscience clause in the Vaccination Act of 1898 and requesting the Local Government Board to reconsider the vaccination laws with a view to making them compulsory. We are glad to see this board of guardians taking a decisive action and although we doubt whether this representation will have the effect which they desire it may do something towards promoting a Bill for revaccination, which in the present state of affairs is much to be desired.

---

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7028 births and 4275 deaths were registered during the week ending Feb. 18th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 17·0 to 21·9 per 1000, declined again last week to 19·5. In London the rate was 19·3 per 1000, while it averaged 19·7 in the 32 provincial towns. The lowest death-rates in these towns were 10·5 in Leicester, 12·1 in Huddersfield, 14·5 in Portsmouth, and 14·9 in Cardiff and in Hull; the highest rates were 25·4 in Birkenhead, 27·7 in Salford, 27·9 in Liverpool, and 28·8 in Preston. The 4275 deaths in these towns included 340 which were referred to the principal zymotic diseases, against 340 and 403 in the two preceding weeks; of these, 92 resulted from whooping-cough, 88 from diphtheria, 64 from measles, 41 from "fever" (principally enteric), 32 from diarrhœa, and 23 from scarlet fever. No death from any of these diseases occurred last week in Huddersfield; in the other towns they caused the lowest death-rates in Plymouth, Leicester, and Bradford, and the highest rates in Swansea, Birkenhead, Manchester, and Halifax. The greatest mortality from measles occurred in Manchester; from whooping-cough in Cardiff, Nottingham, Birkenhead, Halifax, and Sunderland; and from "fever" in Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 88 deaths from diphtheria included 40 in London, eight in Sheffield, five in West Ham, five in Swansea, four in Birmingham, four in Liverpool, three in Birkenhead, and three in Leeds. No fatal case of small-pox was registered last week in any of the 33 large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Feb. 18th, was 2587, against numbers declining from 2939 to 2642 at the end of the seven preceding weeks; 202 new cases were admitted during the week, against 220, 265, and 253 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 348 and 381 in the two preceding weeks, declined last week to 413, and were 63 below the corrected average. The causes of 48, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Bradford, Leeds, Hull, and in 15 other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Swansea, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the four preceding weeks from 21·3 to 31·2 per 1000, declined again to 28·0 during the week ending Feb. 18th, but exceeded by 8·5 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 18·0 in Dundee and 18·6 in Perth to 32·5 in Greenock and 34·5 in Paisley. The 855 deaths in these towns included 31 which were referred to whooping-cough, 14 to diarrhœa, 11 to scarlet fever, nine to measles, seven to "fever," and four to diphtheria. In all, 76 deaths resulted from these principal zymotic diseases, against 95 and 101 in the two preceding weeks. These 76 deaths were equal to an annual rate of 2·5 per 1000, which was 0·9 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 43 and 37 in the two preceding weeks, further declined to 31 last week, of which 11 occurred in Glasgow, 10 in Edinburgh, and four in Leith. The deaths referred to scarlet fever, which had declined from 14 to six in the three preceding weeks, rose again to 11 last week, of which seven were recorded in Glasgow. The nine fatal cases of measles showed a marked decline from recent weekly numbers, and included five in Glasgow, two in Edinburgh, and two in Aberdeen. The deaths referred to different forms of "fever," which had been two and eight in the two preceding weeks, were seven last week, of which six occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 262 and 346 in the two preceding weeks, declined to 285 last week, but were as many as 194 above the number in the corresponding period of last year. The causes of 30, or nearly four per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·8 and 31·6 per 1000 in the two preceding weeks, further declined to 27 during the week ending Feb. 18th. During the past four weeks the rate of mortality in the city has averaged 28·9 per 1000, the rate during the same period being 19·3 in London and 25·9 in Edinburgh. The 183 deaths registered in Dublin during the week under notice showed a decline of 29 from the number in the preceding week, and included eight which were referred to the principal zymotic diseases, against 10 and eight in the two preceding weeks; of these, four resulted from whooping-cough, two from diphtheria, and two from "fever," but not one either from small-pox, measles, scarlet fever, or diarrhœa. These eight deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 1·6 in London and 2·4 in Edinburgh. The fatal cases of whooping-cough, which had declined from five to two in the three preceding weeks, rose again to four last week. The two deaths from diphtheria exceeded the number in any recent week. The deaths referred to different forms of "fever," which had been one and four in the two preceding weeks, declined again to two last week. The 183 deaths in Dublin last week included 27 of infants under one year of age and 58 of persons aged upwards of 60 years; the deaths of infants showed a further marked decline from recent weekly numbers, while those of elderly persons were within one of the number recorded in the preceding week. Six inquest cases and three deaths from violence were registered; and 63, or more than a third, of the deaths occurred in public institutions. The causes of 14, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Staff Surgeons: F. J. Lilly to the *Resolution*; W. Tait to the *Colossus*; and J. R. MacDonnell to the *Mars*. Surgeons: W. Bowden, D.S.O., to the *Trafalgar*, and R. H. Mornement to the *Eclipse*.

ROYAL ARMY MEDICAL CORPS.

The under-mentioned Surgeons on probation to be Lieutenants: Harold Percy Waller Barrow, John Edward Hodgson, Alic Lawiston Scott, Lionel Edmund Longworth Parker, James Geoffrey Gill, George William Grey Jones, Matthew Henry Gregson Fell, Gerald Hamilton Goddard, William Bertram Winkfield, Thomas Champion Lauder, Jonas William Leake, John William Hobart Houghton, Duncan Edward Carme, Herbert Stockley Taylor, George Mills Goldsmith, Richard Harte Lloyd, David Harvey, John Macfarlane Sloan, Henry Evered Haymes, Francis John Brakenridge, George Constantine Phipps, Nathaniel John Crawford Rutherford, Gilbert John Anthony Ormsby, Harry Dixon Packer, Lawrence Humphry, Robert Stuart Rodger, William Watson Scarlett, Horace Kemp Palmer, Arthur Oliver Bird Wroughton, and Frank Ashe.

Colonel J. A. Clery, R.A.M.C., is appointed Principal Medical Officer, Thames and Woolwich districts, vice Colonel R. P. Ferguson. Colonel A. W. Duke, R.A.M.C., is appointed Principal Medical Officer, North-Western District. Lieutenant R. E. G. Phillips joins at Woolwich for duty. Major L. P. Mumby has embarked for India. Major H. J. Barnes assumes medical charge of officers and their families, women and children, at Colchester. The following officers have been posted as follows: Lieutenant-Colonel Carey and Major Berryman to Bengal, Major Marder to Madras, and Major Stables to Bombay.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Andrew Arthur Abraham, 5th Volunteer Battalion the Durham Light Infantry, to be Surgeon-Captain.

INDIAN MEDICAL SERVICE.

The Queen has approved of the restoration of Captain

John Plowden Morton, Madras Establishment, from the Half-pay List to the Effective List.

VOLUNTEER CORPS.

Rifle: 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant C. C. Brodrick resigns his commission. 4th Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant E. H. Sutcliff resigns his commission. 1st Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Lieutenant-Colonel J. McAlister retires under the provision of Paragraph 111 of the Volunteer Regulations, 1898, with permission to retain his rank and to continue to wear the uniform of the battalion on his retirement. 1st Surrey (South London): Richard Jocelyn Swan to be Surgeon-Lieutenant. 1st Wiltshire: Surgeon-Lieutenant P. J. Barcroft resigns his commission.

"THE TRANSPORT OF SICK SOLDIERS."

The above subject was referred to in this column last week. The correspondence has been continued in the *Morning Post* by "Surgeon-Major" who agrees for the most part with our contemporary's previous correspondent and incidentally characterises the military arrangements at the Hospital of Hong-Kong as a "disgrace to civilisation." He however agrees with our contention *that it is the War Office* who are to blame. He says: "But the blame must not be laid on the Army Medical Service, for as matters now stand it is powerless to enforce its own recommendations, the War Office having the right of veto on all matters medical; the saddle must therefore be fitted to the right horse. As I have already stated, I have seen the working of army hospitals in several other countries, and I have no hesitation in stating that our War Office would be well advised if it put some of its obstinate pride in its pocket and went to France, Germany, Japan, Italy, or even Portugal, for some novel, practical, and humanitarian ideas as to how military hospitals should be equipped and worked, for I regret to say that Great Britain is nearly half a century behind the times in this respect. ...... Let the Director-General of this department be given a free hand and then held responsible to the nation for his stewardship. Anything short of this will only land the department in hopeless disaster in a big war."

THE POST OF SURGEON-GENERAL OF HER MAJESTY'S FORCES IN INDIA.

Surgeon-General Gore has arrived in this country from India on having completed his tour of service as principal medical officer in that command. As we have already announced he will be succeeded by Surgeon-General W. Taylor, C.B., who is leaving England to take up the appointment vacated by Surgeon-General Gore. The rumours as to the abolition of the separate post of Surgeon-General of Her Majesty's forces in India and its amalgamation with that of the office of the head of the Indian Medical Service were, as we *predicted would be the case, without foundation.* Colonel Townsend, R.A.M.C., is officiating in the appointment pending the arrival of Surgeon-General Taylor.

SEA TRIPS FOR SICK SOLDIERS.

We learn (on the authority of the *Times of India*) that the Indian Government have accepted the proposal to send sickly British soldiers on sea trips in Indian Marine vessels this season whenever it is possible to *find room for* such men. We congratulate the Indian authorities on their decision, for it is quite a step in the right direction from a medical and hygienic point of view.

THE POST OF PRINCIPAL MEDICAL OFFICER IN EGYPT.

It has, we believe, been settled that a Surgeon-General is no longer needed for the medical direction of the British Forces in Egypt and that Surgeon-General Price who was to have succeeded Surgeon-General Skey Muir will not do so, but that an officer of the rank of Colonel of the Royal Army Medical Corps will be nominated to the post.

DEATH IN THE SERVICES.

Deputy Surgeon-General Henry *R. L. MacDougall, Bombay* Army (retired), at Dunollie, Oban, on Feb. 9th, in his sixty-fourth year.

The following officers of the Royal Army Medical Corps on their arrival in India are to be posted as follows: Lieutenant-Colonel Carey and Major Berryman to Bengal, Major Marder to Madras, and Major Stables to Bombay.

Correspondence.

"Audi alteram partem."

DIFFICULTIES UNDER THE NEW VACCINATION ACT.

To the Editors of THE LANCET.

SIRS,—I was lately required by the usual notice from th vaccination officer of a union in which I am one of th public vaccinators to visit and offer to vaccinate a chil *in my district residing, according* to the notice, five mile from my own residence. I gave the statutory notice b post and in due course made an express visit to the state place of abode but found no such child resident there. was informed that the family had removed into anothe union some 10 or 12 miles distant. Am I not entitled t claim from the guardians in addition to the usual 1*s.* fe payment for my express journey, so fruitless, by some carelessness on the part of their vaccination officer? I shal claim 5*s.* at the end of the quarter.

I am, Sirs, yours obediently,
W. ROBERTSON.

Glanton, R.S.O., Northumberland, Feb. 15th, 1899.

*** The Vaccination Order of 1899 makes no provision fo such a case, and such an occurrence, under ordinary circumstances, should not be possible. The vaccination officer is only allowed to place on the list which he sends to the public vaccinator the names of children to whose houses he has himself just paid a personal visit, and the vaccination officer's action in this matter calls for inquiry. Then, again, a fortnight is given to the public vaccinator in which to make his visits for the purpose of offering to vaccinate children, and the fee of 1*s.* per visit was based on the assumption that he would so arrange his work that all the cases in one direction or locality would be visited on the same day. If our correspondent had a 10 miles' journey to and fro and could only make one such visit, then his district *is* one as to which *it* is quite certain that the Local Government Board would on his application grant more than the minimum fees of 1*s.* and 5*s.*; indeed, they are stated to have done so already in a considerable number of cases.—ED. L.

To the Editors of THE LANCET.

SIRS,—If I read Section 1, sub-section (3) of the Vaccination Act of 1898 aright the public vaccinator referred to by your correspondent "L.R.C.P., M.R.C.S." in THE LANCET of Feb. 18th was not only acting strictly within his rights, but he was performing the duty most plainly imposed upon him by the terms of that much-discussed measure. *"Fathers* in lucrative business" are not exempt from the operation of the Act—dukes and crossing-sweepers alike must own its sway. Yet I feel sure it needs only the relation of a few more such experiences as those of "L.R.C.P., M.R.C.S." and of your other correspondent "P.V." to convince our legislators that the Act is thoroughly unworkable in actual practice. We can but hope that the letters of these two gentlemen may do something to aid the *movement for its* repeal.

I am, Sirs, your faithfully,
M.B. EDIN.

Feb. 19th, 1899.

To the Editors of THE LANCET.

SIRS,—A letter appeared in THE LANCET of Feb. 18th, under the above heading in which "L.R.C.P., M.R.C.S." complains of the public vaccinator of his district. If "L.R.C.P., M.R.C.S." would read through the Local Government Board's Orders under the Vaccination Acts, 1867–1898, he would become aware that his public vaccinator had only carried out those Orders. The work under the new Act, I know, is distasteful to all concerned, not only to parents and family medical attendants, but also to the public vaccinator, who should not be found fault with for doing his duty because that happens to be disagreeable to others besides himself. "L.R.C.P., M.R.C.S." complains of notices of intention to visit and offer to vaccinate being sent to patients "*irrespective of their position*"; the reply is obvious—the only distinction of persons made in the Act is as between those who have been vaccinated before reaching the age of four months (or who hold an exemption certificate or are dead) and those who have not been vaccinated at that time of life. The reply to what is left of the letter is this. Had "L.R.C.P., M.R.C.S." not omitted to renew his postponement when the previous postponement lapsed the vaccination officer would not have sent his patient's name to the public vaccinator and all the sequelæ to which exception is taken would have been avoided, and "L.R.C.P., M.R.C.S." would not have had the present opportunity of expressing his opinion upon the working of the Local Government Board's Orders to vaccinators under contract. One word on the general subject. If medical men who are not public vaccinators would only remember that the latter only carry out orders that they had no hand in framing and which they find are frequently very distasteful it might save much friction and unjust feeling.

I am, Sirs, yours faithfully,

Feb. 21st, 1899. PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—It is with much satisfaction I read that some public vaccinators find the new duties they have voluntarily undertaken irksome. I hope they will continue to find them so, for such work is opposed to the ethical laws which rule our profession and it is satisfactory to read that law-breaking brings its own reward. If a public vaccinator may call on people of whom he knows nothing except that they have a child unvaccinated and offer his professional services, then I may call at any house where I hear there is measles and offer my professional services The public vaccinator accepts the work for the sake of the pay and I might call on a case of measles for a similar reason. If one is unprofessional conduct, the other must be so too.

Most private practitioners by this time have had experience of the public vaccinator calling on sick children, examining them and offering to postpone the operation, quite oblivious of the fact that to examine a patient under another's charge is grossly unprofessional. This outrageous act is compared to the Notification of Infectious Diseases Act, but there is no comparison from an ethical point of view. The latter Act does not seek to legalise "cadging" or encourage it by offering a reasonably good fee if successful and a ridiculous one if unsuccessful. I fail to see how we are to prevent the younger members of our profession from touting for patients with the example of the public vaccinator before their eyes. "S E. District" thinks it even part of his duty to examine and criticise the work of the medical man in charge I doubt if the supporters of the Act ever dreamt of well-to-do people being urged to be vaccinated at the expense of the rates. It is another drop in the bitter cup of the private practitioner that he has to contribute to the rates which pay his rival for attending the private practitioner's patients. My hope is that the Act is too outrageous and objectionable in every way to last long and I hope all private practitioners will point out its errors to as many electors and Members of Parliament as they can, and perhaps we may live to see it repealed.

I am, Sirs, yours faithfully,

Feb 21st, 1899. P. P.

To the Editors of THE LANCET.

SIRS,—Your correspondent "L.R.C P., M.R.C.S.," evidently does not understand the new duties of a public vaccinator. These are irrespective of the financial position of a child's parents and are clearly defined by the Local Government Board in their General Order dated Oct. 18th, 1898. Firstly, the public vaccinator has to visit and vaccinate all those who desire his services, rich or poor. Secondly, when an unvaccinated child is four months and a week old, if the vaccination officer receives no certificate of postponement or of exemption or of insusceptibility and the child has not had small-pox the name goes on a list which is forwarded to the public vaccinator who has thereupon to visit the child, first sending a notice of his intention to do so, and offer to vaccinate it. If the offer is not accepted there is an end of his duty; if it is accepted the vaccination must be postponed if necessary. I take it the child "L.R.C.P., M.R C S." alludes to was over four months old and the name in that case would go on the list referred to above. Possibly the certificate of postponement reached the vaccination officer after he sent the list to the public vaccinator who, of course, should not call again if his offer is refused or if he finds the vaccination has been postponed by the medical attendant. Under certain circumstances the name might appear again on a subsequent list; in this case the public vaccinator would have to act as before—notice, visit, and offer, even if on the previous occasion the offer was refused.

In THE LANCET of Feb. 18th is also a letter giving "The Experiences of a Public Vaccinator." I would like to say that mine, as far as they go, do not agree with these. I have had nothing unpleasant happen and have had 50 names of children sent me to visit and make "the offer" and with "requests from parents" over 100, and in my district I think the new plan is generally liked, especially the domiciliary arrangement. I think with "P.V." that it would be a capital thing if before sending the list it could be found out who wished to accept his services and I quite agree with him as to the very large amount of work under the new regulations. I am, Sirs, yours faithfully,

Feb. 20th, 1899 ANOTHER "P.V."

To the Editors of THE LANCET.

SIRS,—Is it four marks, three marks, two marks, or one mark? As public vaccinator I have had to call on my brother practitioners' patients and offer to vaccinate and I am asked how many places. I say four and am told that they prefer to have their child done in two places by another medical man. Surely those who frame the law must see that such action must *seriously affect the protective statistics of* vaccination and play into the hands of the anti-vaccinationists I call these "half-breeds," as they will not take advantage of the conscience clause and yet are so-called vaccinated.

I am, Sirs, yours faithfully,

Feb. 15th, 1899 *PUBLIC VACCINATOR II.*

To the Editors of THE LANCET.

SIRS,—There is practising in our town an M.D. and J.P. who has recently been appointed parish doctor and public vaccinator. Would you consider it in accordance with the traditions of the medical profession for the above to be calling on the patients of other medical men who have been recently confined and asking them if they would care to have their children vaccinated by him or by their own medical attendant?

I am, Sirs, yours faithfully,

Feb 14th, 1899. M.B.

⁂ This correspondence touches upon many points which are receiving our attention.—ED. L.

THE MIDWIVES BILL OF THE BRITISH MEDICAL ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—The question of legislation on behalf of midwives is about to enter upon its last stage From the very first the promoters of legislation have sought the protection of the woman of the diploma Later, the opponents of legislation sought the control of all women who attended cases of labour whose names were not upon the Medical Register. The proposed legislation is a compromise. An experience of the subject which may fairly be claimed to be many-sided has led me more and more to the firm belief that if the public weal is to be considered of the first importance any legislation which invests uneducated women with a diploma entitling them to practise midwifery, even under restrictions, is fraught with very great danger; my own experience is further supported by the facts frequently published in the newspapers. It is perhaps of some utility to consider how the present state of affairs originated. The Obstetrical Society of London—or, to be correct, its council—has for many years sold a diploma to those who passed an examination. It has also been the main fomenter of agitation in favour of the midwife from the outset. The proposal for legislation has therefore come from the medical profession or from part of it. The society, judging from Dr. Cullingworth's address, has sold its diploma without any code of rules and regulations to be observed by midwives holding it until the present year.

It is a matter of difficulty to distinguish between the society which covers the practice of midwifery by persons who are not upon the Medical Register by means of a diploma from which an income is derived and medical practitioners who cover the practice of unqualified assistants and derive an income from their work. However, the position of affairs now arrived at is this: registered practitioners individually are not allowed to employ unqualified assistants. Associations of registered practitioners are allowed to cover the practice of unqualified practitioners in midwifery by means of a diploma from the sale of which some registered practitioners derive profit. To put matters in order legislation is demanded by such associations and actively pushed forward.

The main body of the profession, at first somnolent, is at last roused and protests and in the result a compromise is so far embodied in a Bill. It is a matter of common notoriety that the restrictive clauses inserted by the British Medical Association are practically not accepted by the principal promoters of legislation, and moreover that the House of Commons is not a body which is likely to pass restrictive clauses in such a Bill. If a case is made out for the resuscitation of the midwife the House of Commons will probably not restrict her practice. This condition of affairs is, indeed, serious, and it is not easy to find a remedy so late in the day. The birthright of the medical profession has been sold for a mess of diplomas to midwives. If it had not been useful legislation might have been put forward solely upon the basis of control over the practice of all persons who practised midwifery and who are not registered medical practitioners, and legislation upon this basis would have had nothing but support from the medical profession. However this may be, I do not believe for an instant that any attempt to pass the restrictive clauses in the present Bill will be successful, and as a matter of strategy if the medical profession desires to secure the insertion into the Bill of proper restrictions it will have to make it clear to the Members of the House of Commons that control over the practice of midwives is what is required and not the formation of a midwife *brigade* sanctioned by Act of Parliament.

If the present Bill is passed I can see no end to the practical difficulties of its working. A Bill of very few clauses could be framed to control the midwife and to effectually protect the ignorant. It required a Bill of the present size to conceal the intentions of the real promoters and to do a great deal of harm.

I am, Sirs, yours faithfully,

LOVELL DRAGE.

Hatfield, Feb. 21st, 1899.

To the Editors of THE LANCET.

SIRS,—Judging from your leading article in THE LANCET of Feb. 18th it does not appear that you consider a "Midwives Bill" altogether desirable. I cannot help regretting that the influence of your important journal was not rather employed in opposing than in apologising for the proposed legislation. While admitting that the Midwives Bill of the British Medical Association is better than any of the other Bills hitherto put forward I thought it my duty to oppose it when before the Parliamentary Bills Committee for the following reasons: (1) because the great majority of the medical profession are opposed to any such Bill; and (2) because in my opinion it increases the public danger rather than lessens it.

The midwife, especially when occupying the responsible position in which such legislation will place her, can always justify her omission to summon medical assistance in unnatural labour by pleading that she thought the labour was normal. Experienced medical practitioners cannot always diagnose unnatural conditions during childbirth at an early stage and sometimes have to confess that they have lost valuable time through such mistakes. How, then, can it be expected that even the best of the proposed registered midwives should be able to avoid them? It has been repeatedly shown that the medical practitioners in the country are amply sufficient to attend to all cases of labour, and it seems to me that the better policy would be to limit the practice of midwives rather than to extend it, as any such legislation as this must inevitably do. No matter how we look at it, a registered midwife will be a State-recognised practitioner of midwifery; and if the Act of 1886 laid down any principle it was that practitioners in one branch of medicine should cease to be licensed by the State. This principle has been unanimously accepted by the profession and it seems most impolitic to weaken it by legislating in the opposite direction. It is very unlikely that any Midwives' Bill will be seriously considered by Parliament this session, and were the profession united in its opposition I believe it might be defeated altogether. The education of midwives is improving yearly and will continue to do so without further legislation; a system, too, of local registration would do much of the good that this Bill proposes and would not be open to nearly so many objections.

I am, Sirs, yours faithfully,

MAJOR GREENWOOD, M.D. Brux., LL.B. Lond.

Feb. 20th, 1899.

"A FATAL CASE OF LITHÆMIC POISONING."

To the Editors of THE LANCET.

SIRS,—Dr. C. R. Elgood's admirably written "Note on a Fatal Case of Lithæmic Poisoning" in THE LANCET of Feb. 18th raises one or two interesting points. In the first place I am doubtful as to whether the case is quite correctly designated as one of lithæmic poisoning—i.e., as being due to the poisonous effects of uric acid or its compounds while in solution in the blood. In my opinion, judging from the graphic description given by Dr. Elgood, the recurrent attacks were due to irregular gout, and as such were probably caused by deposition of sodium biurate in the organs and tissues affected. This view is borne out by the patient's strong family history of gout, by the nature of the attacks, by the extreme anorexia, by the condition of the pulse, by the occurrence of venous thrombosis during two of the attacks, and by the occurrence between the seizures of what were in all probability two slight attacks of regular gout in the great toe. My own view entirely coincides with that of Sir William Roberts that as long as uric acid, whether in the form of sodium quadriurate or biurate, is in solution in the blood it exerts no toxic effect. The other interesting point is as to whether there was in this case any increase in the elimination of urates. I believe that it is frequently misleading to infer that the elimination of uric acid is increased, because small quantities of urine laden with amorphous urates are passed. In this case during the attacks the quantity of urine eliminated apparently averaged about 20 ounces only and was of high specific gravity. I have frequently found among gouty and other patients who have been passing similar small amounts of urine laden with amorphous urates that on estimating the total output of uric acid for each 24 hours it has been found considerably below the normal output.

I am, Sirs, yours faithfully,

ARTHUR P. LUFF, M.D. Lond.

Weymouth-street, W., Feb. 20th, 1899.

"SEWER VENTILATION."

To the Editors of THE LANCET.

SIRS,—Your brief editorial notice of the dangers arising from the foul air discharged from the sewers and their ventilation pipes revives a recollection of a project which I started in 1858. At that time I was medical officer of health of Shoreditch, then a typical insanitary district. I venture to send you a brief summary of my action in the matter. The practical study of sewers—I spent some hours in main sewers amongst other experiences—led me to consider whether some effective means could not be found to lessen the noxious properties of the gases as they escape from the sewers. It appeared to me that the absorptive property of animal charcoal might be turned to account. I proposed that cages of iron containing a layer of coarsely divided animal charcoal, through which all the air emerging should filter, be fitted to the gullies. There are many places where such cages might be fitted without difficulty. In an analogous manner the plan largely adopted of relieving the sewers of the pressure arising from the accumulation and decomposition by discharge-pipes carried up the sides of high buildings, would be deprived of the serious objection that the gases find their way by diffusion into the upper windows of dwelling-houses. The disposition of charcoal-beds in these pipes would render the gases less obnoxious when discharged. I also suggested on behalf of the men whose occupation compels them to enter the sewers that the effect of Dr. Stenhouse's charcoal respirator should be tried. Afterwards Letheby advocated the same plan. The difficulty appeared to be to secure the charcoal filtering apparatus from being choked up with mud I constructed a design which I believed would obviate this and other objections, so that the principle might be applied at a moderate cost to any gully under the street level, thus avoiding all obstruction to traffic —I am, Sirs, yours faithfully,

Feb 18th, 1899 ROBERT BARNES, M D Lond

"THE SURGICAL AID SOCIETY AND ITS METHODS"

To the Editors of THE LANCET

SIRS —With reference to Mr H Betham Robinson s letter under the above heading in THE LANCET of Feb 18th will you permit me to say that the letter in question was the first intimation I had had of any dissatisfaction in regard to the case to which he therein alludes, but I am now in correspondence with Mr Robinson and have no doubt that the explanation of the contingent circumstances will fully satisfy him as to the society s action? In the meantime, may I say for the information of your readers and in answer to the question asked by Mr Robinson that this society does as stated in its prospectuses and other publications, accept the certificate of any duly qualified surgeon and indeed, a form for that specific purpose is provided at the foot of each letter of recommendation for the benefit of patients who are unable to attend here It will however, be evident that this rule, like all others, is liable to exceptions under some special circumstances —I am, Sirs, yours faithfully,

RICHARD TRESIDDER Secretary

Salisbury square Fleet street E.C Feb 21st 1899

A MEMORIAL TO THE LATE PROFESSOR KANTHACK

To the Editors of THE LANCET

SIRS,—The premature death of Dr Kanthack has been so much felt by his numerous friends that we have received letters from many quarters suggesting the propriety of raising a fund to commemorate his work It is probably not generally known that, largely on account of his generous expenditure of money in his various researches, he had not been able during the few years in which he was in receipt of an adequate income to provide sufficiently for his widow

It is therefore proposed to raise a fund the interest of which shall be devoted to the use of Mrs Kanthack during her life whilst the capital amount can eventually be employed in founding some permanent memorial to the late Dr Kanthack All who desire to contribute to the fund are requested to send subscriptions to *Dr Drysdale*, 25, Welbeck street London, W

We remain, Sirs, yours truly

HENRY T BUTLIN
ANTHONY A BOWLBY
J H DRYSDALE

"REGINA v REICHARDT"

To the Editors of THE LANCET

SIRS —Once more the vexed question of certification or no certification in early stages of actual or threatened mental alienation has forced itself upon the public attention and it seems, in view of a forthcoming amendment of the Lunacy Acts, as if the present were a favourable time to endeavour to settle it once for all upon a practical, common sense, and definite basis There are, of course a considerable proportion of the cases of mental disorder constantly arising in which even from the commencement the morbid manifestations are of so pronounced a character that doubt does not for one moment arise regarding the proper course to be adopted, with such cases I do not propose here to deal—they do not come within the scope of the present communication The Lunacy Act 1890 although by no means a perfect Act in every respect, amply and intelligibly provides for dealing with them It is, however an altogether different matter when cases presenting less marked or pronounced symptoms occur in private practice The ordinary medical attendant may well be at a loss to decide exactly what is best to be done to ensure his patients well being and safety consistently with the required non publicity usually a first consideration with families under such circumstances Naturally however, he proceeds to do all that he considers necessary for his patient he may even feel obliged to turn the house temporarily into a kind of asylum, and by placing a sufficient number of attendants or nurses at once entirely deprive the patient of his liberty and ensure his safety. Yet under such circumstances I do not think the necessity for certification or notification would be suggested by anyone But sooner or later a time probably comes when change from home surroundings is considered a necessity and then the conditions become entirely altered, the question not only of deprivation of liberty, more or less complete, but also of pecuniary payment for services rendered to the patient arises and I think it is worthy of discussion whether from the moment it is decided to remove a patient from home care to the care of others, be they medical or other custodians, for payment that there should arise the necessity of some notification of the fact to a central authority, just as in all cases of admission to asylums public or private and hospitals such notification is required to be made within 24 hours

In the absence of some such provision no opportunity is given for adequate supervision of the many hundreds of cases scattered throughout the country in unrecognised confinement, and ample opportunity is thus afforded for abuses, against which the Lunacy Acts, however stringently they may be framed, afford no protection,

I am Sirs, yours faithfully,

Feb 14th 1899 M D.

THE ACCURACY OF THE MEDICAL REGISTER

To the Editors of THE LANCET.

SIRS,—I have received a card requesting my interest on behalf of the widow of the late Frederick W Wilson M B Lond who died at Blackheath in 1894 This name appears not only in Churchill s Directory for 1899 but in the Medical Register for 1898 published more than three years after the death of Dr Wilson I was under the impression that it was part of the duty of a registrar of deaths to send information to the registrar of the General Medical Council of the death of a medical practitioner registered by him The name does not appear in the general register of the University of London Why should it be retained in the Medical Register?—I am Sirs, yours faithfully,

Feb 20th 1899 M R C S, L S A

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

Examples of Immunity from Plague —The Progress of the Epidemic —The Plague Commission —A Proposed International Sanitary League —Inoculation for Typhoid Fever

EUROPEANS have the reputation of a partial immunity from plague This seems to be borne out not only with regard to liability to infection but also with regard to their better chances of recovery Quite apart from racial differences two other classes in Bombay have shown a remarkable immunity during the successive epidemics These are the prostitutes and the street-sweepers *The former are chiefly resident in one* of the most crowded quarters of Bombay and they consist of various races and nationalities In the absence of any register it is impossible to give the precise numbers, but they are placed by those conversant with the district at between 6000 and 7000 Only one case of plague is said to have occurred among them The medical officers and visiting justices actively engaged in searching for cases of plague found none among this class These people come from various parts of India from Bagdad, from Constantinople from Persia from Japan and from South-eastern Europe It is not very clear to what they owe their apparent immunity The houses in which they live are described for the most part as clean well lighted, and well ventilated the doors and windows being kept open till the small hours of the morning This alone, however, is not sufficient to account for the occupants escaping infection, because it is said that in the neighbouring streets as many as 27 bodies of the victims of the epidemic have been taken out of a few houses in one morning

On the other hand, the clean, well-ventilated houses of the richer and more advanced natives have also escaped. It has been suggested that plague is innocuous in the presence of certain other diseases, such as leprosy and syphilis. This is not absolute as regards leprosy because lepers have been recorded as dying from plague. Whether persons suffering from syphilis are exempt from plague is not known. I know of no observations indicating this. One would hardly suppose that syphilis would give a life-long protection against plague even if it had this effect during its primary and secondary stages. That syphilis is very common amongst prostitutes in Bombay is admitted, and it is possible that an individual protection of this character combined with the more sanitary conditions of existence might account for the extraordinary exemption. At one time it was thought that it was not the syphilitic poison which protected against plague but the saturation of the system with mercury and on this basis many plague patients were treated almost to salivation. No beneficial results followed from this line of treatment even when employed hypodermically as well as locally. It is curious to note that at the time of the plague in the sixth century at Constantinople the wicked and the profligate were reported to escape from the ravages of that epidemic.

The other class—viz., the street-sweepers—has had a partial immunity from plague. These people with their families number over 1000. They live in small rooms and are very crowded. Their occupations, however, keep them out of doors. In the three years of the plague the number attacked has only been 21 and of these eight recovered. They were not isolated or segregated as other people were for fear of a general strike amongst the whole class. They are as crowded and as dirty as other people and they live in a plague infected district.

Plague is apparently inclined at the moment to increase again in the north and in the centre of the Bombay Presidency and to disappear from the southern portions. The net result in the week's returns shows a slight increase. There have been 2388 cases and 1872 deaths. The total mortality in Bombay city from all causes for the week ending Jan. 31st was 1601. This is an increase of 153. In all probability 1000 of these deaths were due to plague, because the average weekly death-rate for Bombay is under 600. The deaths actually recorded as of plague were only 538, but little reliance can be placed on the number registered as plague although there were 140 more recorded than for the previous week. This outbreak appears to be about a fortnight later in the season than that of last year and the outbreak of 1897–98 was about six weeks later than the first outbreak of 1896–97. Reports from the hospitals in Bombay show that the type of the disease is now very virulent, that patients are left to the late stages before being brought to the hospital; and that a great many come in a moribund condition.

The death-rate in Madras city is again abnormally high, that for the past week being at the rate of 49·3 per 1000, as against an average of 36·8 per 1000. There is no plague.

There seems to be a likelihood of a recrudescence of the plague in Karachi. Cases have occasionally occurred ever since the last outbreak and Karachi has not been able to clear itself, but during the past week several cases have been heard of in different quarters of the city. Fear has again seized the inhabitants who are beginning to flee in large numbers. The possibility of the obnoxious plague restrictions being re-introduced has hastened the exodus.

The value of railway medical inspections as of port inspections seems to be chiefly in preventing sick people of all kinds from travelling. As regards plague 11 cases only were detected during the week at all the railway inspection stations in the Presidency, so that with respect to this disease all the trouble, expense, and inconvenience involved are not counter-balanced by important results.

The Plague Commission has been at work in Karachi and Cutch Mandvie and will take evidence again in Bombay before leaving for Europe. Very few facts of any importance are reported. Dr. McMullen attributed the recrudescence in Kotri during the cold weather to the bringing out of infected clothing stored away during the summer when the epidemic prevailed. Dr. Mackenzie said that malarial fever was generally common at Karachi but that during the plague visitation there had been a marked decline. Mr. V. E. Nazareth gave an account of the treatment by Roux's serum. He said that 47 persons were inoculated, of whom 25 recovered. It almost invariably failed in pneumonic cases. (The reports do not mention that these cases were picked out and that they were not taken as the consecutive admissions to the hospital.)

Prince Orbeliani, a Russian nobleman, proposes to establish an international sanitary league to supply a complete staff of bacteriologists, medical officers, chemists, and nurses (all of whom have gone through training in actual contact with epidemics) to deal with outbreaks in any country that may be affected. The prince sees no reason for counting absolutely on the supposed immunity of Europeans in the present day against plague which formerly carried off the populations of European cities by the hundred thousand. Large numbers of people in European countries, he argues, live in conditions almost as favourable to epidemics of plague as those that prevailed when London, Moscow, Marseilles, Milan, and Naples were scourged by it. In order to meet a danger which affects all countries alike in large measure it is suggested that the means of resistance should be placed on a better footing than now obtains. He argues that the danger threatening all countries ought to be encountered by the organised sanitary resources of all countries working together for the common safety.

Inoculation against typhoid fever seems so far to have been very successful. Professor Wright (Netley), one of the Plague Commissioners, inoculated a large number of soldiers at Rawal Pindi and in the course of a lecture he gave instances of its value. He reminded his audience that 1500 troops were attacked with it in India every year and that 300 died. He alluded to the Maidstone epidemic and stated that of the 200 nurses and attendants at the lunatic asylum 95 were inoculated, not one of whom took typhoid fever, while of the remainder who refused to be inoculated 19 suffered from the complaint and died. He instanced also eight young subalterns who went to Khartoum. Six of these were inoculated; the other two took their chance. Both of the latter were attacked with fever and one died; the six others remained well. The symptoms following inoculation were malaise and slight fever lasting generally not longer than 24 hours. 3000 troops have now been inoculated.

Feb. 4th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Death of Mr. W. T. Crabbe, F.R.C.S. Edin.

THE death of Mr. Crabbe, which took place on Feb. 13th, has caused a deep feeling of regret among a large number of people. Mr. Crabbe, who was 55 years of age, began his professional life with great promise. As a student at Edinburgh he gained a silver medal in physiology and a gold medal in medical jurisprudence, after which he became a Fellow of the Royal College of Surgeons, Edinburgh, and a Licentiate of the Royal College of Physicians, Edinburgh. With prospects of a successful career he devoted his talents to the cause of medical missionary work, and after experience in this direction at Edinburgh and at Aberdeen he was appointed superintendent of the Medical Mission at Birmingham in 1876. Here among the poorest and most destitute he laboured earnestly with unflagging zeal. Under the continued strain of over-pressing needs his health broke down in 1896, the symptoms being mainly referrible to the liver. A sea voyage and long change failed to restore him to his former energetic condition and though he worked assiduously with the same ardent spirit of devotion he suffered from another attack last December to which, in spite of the greatest care, he succumbed. His life leaves a record of a high sense of duty and an unselfish fidelity to the cause he had so much at heart. He leaves a widow and three sons, two of whom are medical men.

Health Visitors.

The Health Committee have issued an advertisement for the services of four women as health visitors for the city—their duties to comprise visiting from house to house in the poorest parts of the city, calling attention to the necessity for cleanliness of the house and its surroundings, giving advice as to the rearing of children and the nursing of the sick, distributing and explaining handbills on the prevention, &c., of infectious diseases, and reporting daily to the medical officer of health. They will be required to reside in or near the respective districts in which they work. Their age is not to exceed 35 years and their salary is to be 25s. a week with uniform. This is an opening which admits of much good being done among the poorer classes, but one which evidently will require much tact and discrimination in its pursuit. An intelligent knowledge of the duties to be performed and the power of explanation are not always to be readily found even among the educated classes. It is observable that in some of the advertisements the proposed *visitors* are called "women" and in some *others* "ladies"—a difficulty evidently presenting itself to the minds of those responsible for drawing up the notices.

The Inebriates Act.

The utility of the Act passed last session appears so far to be a dead letter. Cases are constantly occurring at the local police-courts which show that an institution for the reform of this vicious habit is strongly needed. The statute empowers magistrates to send habitual drunkards after a certain number of convictions to an inebriate reformatory where they may be kept for any period up to three years. At present the authorities have provided no places of the kind, nor has any step been taken by individual or combined enterprise for this salutary object. Careful and unprejudiced consideration would show the great advantage of these powers duly exercised. A vast gain to the community would result from the deprivation of the opportunities for recurring drunkenness with all the train of moral and social evils which surround the victims of repeated indulgence.

Health Lectures.

Under the auspices of the Athletic Institute a grand opportunity for advertising is offered. What more attractive headings could be placarded about the town than the following with the names and titles of the lecturers in full: "The Foot and its Covering"; "Sudden Illness—what to do"; "Some Points in the Structure and Care of our Eyes, Ears, and Teeth"; "On Elementary Nursing"? Truly it may be said, "Which of our learned with all his lore hath leisure to be wise?" Advice gratis is the next consideration and the value will be accordingly; in the meantime the public are to be educated to get good for nothing.

Feb. 21st.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Annual Meeting of the Manchester Royal Infirmary.

AT the annual meeting of the Manchester Royal Infirmary held on Feb. 10th one sentence in the report gave rise to some rather animated discussion. It was to the effect that the strain on the resources of the institution had "been less than in some preceding years and with but few exceptions applications for admission and accommodation of patients have been readily met." It is curious that the gentleman who seconded the adoption of the report seemed to prove conclusively that the statement was inaccurate and misleading. Dr. Leech moved that it should be omitted and said he could not help feeling that it "would never have appeared had a representative of the acting medical staff been present when the report was drawn up." It shows very prettily how untrustworthy figures are without explanations that will show their true bearings. In the book in which cases "deferred" for want of room are kept 1029 are entered for 1896, 250 for 1897, and only 57 in 1898, but the report did not state that this fall in the numbers arose from a change in the mode of classification and from the great use made of the Cheadle Convalescent Hospital as a sort of "relief train." In truth, the Cheadle Hospital is, from the strain on the infirmary, in danger of becoming more and more an "overflow" than a convalescent hospital, as patients are often sent there when it would be better to keep them longer in Piccadilly. Dr. Leech gave several instances where urgent cases had to be sent away for want of beds. Mr. Thomas Jones, professor of surgery, seconded the amendment and said that those who worked within the infirmary knew the great pressure to which the accommodation was subjected. Patients had to be sent to Cheadle where they had not the requisite nursing staff who ought to remain at the infirmary. Dr. Renaud said the board asked him to draw up the preface to the report and he was responsible for the statement which had received the sanction of his colleagues, referring of course to his lay and not his medical colleagues, for he is still one of the consulting physicians. Dr. Harris, in supporting the amendment, said that it was a notable thing that 14 of the active staff should agree that the paragraph objected to was misleading. The amendment was agreed to. The matter is chiefly of importance as showing how injuriously the present state of things is affecting the infirmary as an agency for the relief of human suffering. The negotiations with the corporation are hanging fire. One of the gentlemen present urged that they should be pushed on and that the board should say what they are willing to accept for the site and the corporation would then say whether or not they were prepared to pay it. If nothing is done the present deadlock will soon become a scandal.

Manchester and Salford Sanitary Association.

The annual meeting of the Manchester and Salford Sanitary Association was held on Feb. 13th and the work of the year reviewed. Having no executive power the association can only work by educating and influencing public opinion and—let it be said with all humility—by bringing similar influences in regard to public health to bear on the city council. It has to be acknowledged that hitherto it has been labour in vain so far as cottage baths are concerned. This question has for several years been brought before the Baths Committee. The city has many public baths on a large scale so palatial, however, as to be deterrent to poor women who would gladly wash themselves and their children in a cottage. It would cost little and do much good to provide available means of removing from many of the fellow citizens of the Baths Committee the reproach and offensiveness of personal filth. But the average city councillor loves to do *some great thing*. Miles Platting and Ancoats have long been distinguished as the special home of bad smells and in consequence of representations from these districts a joint *deputation* waited on the Sanitary Committee of the corporation and were told that efforts were being made to correct these nuisances which, besides being disgusting, are often distinctly injurious to health. The association did not approve of the action of the corporation in one case of complaints of bad smells from sewers "in sealing up six of the manholes and thus leaving nearly two-thirds of a mile of sewer highly charged with naphthalene, benzol, &c., without any ventilation whatever." Arising out of these nuisances from works dealing largely with gas by-products the question is being discussed of these being dealt with by the corporation itself, with the twofold object of profit to the ratepayers and a guarantee of having the work carried on in the least offensive way. Much interest has been taken in the question of lamp accidents and the investigations of Mr. William Thomson, F.C.S., carried on for about two years, resulted in a strong expression of opinion that the flashing-point of the oil should be raised. It would no doubt still be desirable to prevent the use of dangerous and ill-constructed lamps. It may fairly be said that the association has often been in advance of public opinion and in nothing perhaps is this more clearly shown than in the "campaign against phthisis" which has been carried on for many years, long indeed before it became popularised and fashionable. The corporations of Manchester and Salford have been urged to make provision "for the more effective treatment of consumptive patients in suitable premises." It is in contemplation to arrange for a general conference on the subject to which all local authorities in the district and representatives of boards of guardians, hospitals, &c., will be invited. The association is also giving its support to the efforts of the corporation to prevent the sale of milk containing the tubercle bacillus. The long-continued struggle with the smoke nuisance still goes on and in Manchester with some little success, but Salford continues a gross offender which is rather hard on Manchester as the prevailing winds bring the smoke across the narrow boundary of the Irwell, which, by the way, is still as black as the smoke which passes over it. An appeal for funds ought not to be necessary but it is so, though most of the work is done without fee or reward, if "the modest standing expenses" are to be met, for Manchester owes much to the association.

Prevention of Tuberculosis.

At a meeting of the North-Western Branch of the Incorporated Society of Medical Officers of Health held in Manchester on Feb. 10th, Professor Delépine read a paper on the Prevention of Tuberculosis, which was followed by a discussion. He urged the "notification of the occurrence of tuberculosis—more especially of the most infectious form, phthisis—in the same way as other contagious maladies were notified." He considered "the establishment of sanatoria for the treatment of consumptives was a wrong measure because it passed over the most important preliminary step by which the sources of infection should be discovered." This statement, as reported, has led to some misapprehension which possibly would have been avoided if notification had been spoken of as a necessary first step. There was an almost unanimous agreement as to notification, in favour of which Dr. Niven (Manchester) spoke strongly, followed by Dr. Howarth (Darwen), Dr. Wheatley (Blackburn), Mr. Vacher (Cheshire), Mr. Berry (Wigan), and Dr. Hayward (Haydock). A resolution in favour of notification as a necessary preliminary to further action was carried after further discussion, the chairman only, Mr. Pilkington of Preston, voting against it. He thought the expense would be prohibitive, that "the disease ran too long a course, and it would not be possible to shut up phthisical persons who needed to be out-of-doors." While admitting the desirability of all necessary precautions against the spread of tuberculosis by the disinfection of rooms and houses and by proper and scrupulous care on the part of the patients it must be acknowledged that here compulsory notification is by no means so simple as in the case of small-pox. The chairman illustrated the sort of difficulty that would be met with by saying that "notification suggested a state of things in which a man with tuberculosis would not be able to cough in public without first ringing a bell." But some of the more ardent spirits would object entirely to his appearance in public.

Feb. 22nd.

SCOTLAND.

(From our own Correspondents.)

The Death of Professor Rutherford.

The death of Professor Rutherford, which occurred on Tuesday last, has cast a shadow over the University. At a meeting of the students a resolution has been passed expressing their sense of the deep loss sustained by them in the death of their distinguished teacher, and it was resolved to place a bust of Professor Rutherford in the physiology class-room.

Edinburgh University Court and the Lectureship on Tropical Diseases.

At the meeting of the Edinburgh University Court held on Feb. 13th the Court resolved to invite applications by advertisements for the office of lecturer on tropical diseases and remitted to a committee to consider and report as to the qualifications of the candidates, the first appointment to be for a period of three years which may be renewed. The following are the regulations pertaining to the lectureship: "1. The course of instruction shall extend over not less than 20 or more than 25 lectures and shall consist of lectures and demonstrations and other practical work, the number of meetings for each to be arranged by the Senatus. 2. The class fee for the course shall be £2 2*s.*, with an entrance fee of 5*s.* in the case of non-matriculated students. 3. Two such courses shall be given in each year, one in the winter and the other in the summer session, should a course in each session be required. 4. Each course of instruction shall be open to (*a*) qualified medical practitioners; (*b*) students who have completed the curriculum for the final examination in medicine of any of the qualifying medical authorities; and (*c*) others especially interested in the subject. 5. Certificates of attendance will be granted as follows: (*a*) a class certificate to each member of the class who has performed the work of the class in a satisfactory manner; (*b*) a University certificate to be signed by the Dean of the Faculty of Medicine to each member of the class who has attended a course of instruction on practical bacteriology, including the micro-organisms of tropical diseases, who has also attended the course of instruction in tropical diseases, and who has performed the work of both of these classes in a satisfactory manner. This certificate shall be based on evidence received from the teachers on practical bacteriology and tropical diseases." Applicants are required to lodge 20 copies of their application and 20 copies of their testimonials with the secretary of the University Court not later than March 6th. One copy of the application should be signed. At the same meeting the court recognised as extra-academical teachers whose courses of instruction qualify for graduation in medicine in the University, the following lecturers: (1) Professor W. E. F. Thomson, Anderson's College Medical School, Glasgow (Physiology); and (2) John Macpherson, M.D. Edin, Larbert (Mental Diseases).

Edinburgh Town Council and the Milk-supply.

The Public Health Committee of the Edinburgh Town Council on Feb. 14th, on a motion by Baillie Pollard, resolved unanimously to recommend the magistrates and council that it should be especially stipulated in the contracts for the supply of milk to the various city departments: "That cows from which milk is taken for the contract supplies shall have withstood the tuberculin test applied by a qualified veterinary inspector approved by the Town Council."

Edinburgh Ear, Eye, and Throat Infirmary.

At the annual meeting of the Edinburgh Ear, Eye, and Throat Infirmary held on Feb. 15th the report announced the resignation of Dr. Kirk Duncanson, the senior medical officer. Dr. Duncanson's connexion with the infirmary dated from 1870 and from 1875 till 1883 he conducted the Ear Dispensary at his own expense. The report also stated that the total number of patients treated during the year was 2509, an increase of 194 over the number for the previous year.

Edinburgh Parish Council and Phthisical Patients.

The Edinburgh Parish Council, like the Town Council, is engaged in considering the question of arrangements in connexion with phthisical patients. While the Town Council has to concern itself more with prevention of consumption the Parish Council has to consider the question of accommodation, &c., for those who have fallen on its hands for relief when incapacitated by the disease. No less than 38·9 of the deaths from phthisis in Edinburgh take place among persons living in houses under £10 rental, so that a large number of those dependent on the parish are placed in that position directly or indirectly from the effects of this disease. The Council are considering the question of building separate wards for phthisical patients in connexion with one or other of the poor-houses. A site to the west of Craiglockhart poor-house is considered to be the most suitable one in the event of the Council deciding to erect such wards.

Royal Edinburgh Hospital for Sick Children.

The fortieth annual meeting of the contributors to the Sick Children's Hospital was held on Feb. 20th. The report showed an increase in both out-patients and in-patients, this being especially seen in the case of the out-patients, of whom 700 more new cases had been treated than in the previous year. The necessity for providing further accommodation in the out-patient department is still engaging the attention of the directors. A new surgical ward had been opened during the year. The report of the medical staff showed that about one-third of the in-patients were under two years of age and the staff were of opinion that on this account an increase in the nursing staff was justified. One-third of the total mortality was due to tuberculosis in one form or another. The chairman in moving the adoption of the report mentioned that the cost per child in the institution this year had been £4 17*s.* 1*d.*, as against £5 0*s.* 4*d.* in the preceding year. They were not in that country, as in England, troubled with conscientious objectors, there having been an increase of about 50 per cent. in the number of vaccinations.

Memorial to Professor Coats.

A fortnight ago, as was announced in The Lancet, a meeting was held at which it was resolved to raise a fund for a memorial to the late Professor Coats. A proposal was then adopted that it should take the form of a University prize or scholarship in connexion with pathology. To carry out this a sum of at least £1200 will be required. Circulars are being issued calling for subscriptions, but as many of Dr. Coats's friends and former pupils, who are widely scattered, may not be reached in this way, those who are managing the fund desire to intimate that contributions will be received and acknowledged by Dr. David Newman, honorary secretary, 18, Woodside-place, Glasgow, or Mr. James J. MacLehose, honorary treasurer, 61, St. Vincent-street, Glasgow.

University of Glasgow.

The open university lecture on Feb. 20th was delivered by Dr. John Glaister, Professor of Forensic Medicine, the subject being "Microbes." The lecture was largely attended and was abundantly illustrated by lantern slides, culture preparations, and other specimens. In the course of his remarks Professor Glaister referred to the present day crusade against tuberculosis, and expressed the opinion that much good would result from it provided the effort was a continuous one and was linked with practical methods. Among the conditions to be demanded he included the extermination of tuberculous milch cows from herds the milk of which was used as food by man and especially by children; the education of the public to the fact that by the boiling or sterilisation of milk possibilities of harm from this source were much reduced; the compulsory inspection of meat; popular instruction on the essentially infective nature of tuberculosis and especially of the dangerous character of the expectoration of phthisical patients; and the efficient promotion of municipal and domestic sanitation.—The list of those on whom the Senatus proposes to confer honorary degrees at the April graduation has just been published. Amongst those who are to receive the degree of LL.D. is Mr. James Finlayson, M.D., Glasg., Lecturer on Clinical Medicine in the Glasgow Western Infirmary and Honorary Librarian to the Faculty of Physicians and Surgeons. Sir Henry Irving is to be honoured with the same distinction.

Medical Vacancies.

The position of visiting physician to the Glasgow Training Home for Nurses is vacant, Dr. T. K. Monro's term of office having expired.—The committee of the Royal Hospital for Sick Children have determined to appoint two additional extra physicians.

Memorial Window to Principal Caird.

At a meeting of the committee in charge of this memorial held in Glasgow on Feb. 13th it was decided that the window should be placed on the east side of the Bute Hall in Glasgow University directly opposite the McGrigor window. It was also decided that the design should consist of 12 figures arranged as follows: First row—Plato, Aristotle, Spinoza, Hegel; second row—Athanasius, Chrysostom, Augustine, Aquinas; third row (below the gallery)—symbolical figures representing Philosophia, Jurisprudentia, Medicina, Theologia. The total cost, including all expenses, will be fully £900. The subscriptions to date amounted to £833. Subscriptions of past students had been received from Newfoundland, Canada, South Africa, British East Africa, India, and the Argentine Republic. Those who still desire to contribute are requested to send their subscriptions as soon as possible to the honorary secretary, Mr. Archibald Craig, 156, St. Vincent-street, Glasgow.

University of Aberdeen.

The University Court has resolved to appoint a lecturer on tropical medicine, his remuneration to come from the fees. It is proposed that the course should consist of about 25 lectures as a preliminary for the curriculum in the London school.—Mr. Stout, Anderson lecturer on comparative psychology, will resign the lectureship at the close of the present session.—With reference to a memorial signed by 425 students requesting the Court to provide a gymnasium, the Court has expressed sympathy with the object and remitted the memorial to a committee with the view of taking the earliest opportunity of providing a gymnasium and to report.—In deference to the wishes of the University authorities the Secretary for Scotland has agreed to make no recommendation for a few weeks as to filling up the chair of Natural History vacant by the death of Professor H. A. Nicholson, the object of the delay being to allow opportunity for considering the possibility of separating the subjects of zoology and geology.

Public Health in Aberdeen.

Practically all the local authorities in Aberdeenshire and Kincardineshire and several in Banffshire and Nairnshire have agreed to join in the arrangement recently made between the Aberdeen Town Council and Professor Hamilton, Aberdeen University, for the conducting of bacteriological investigations in connexion with infectious diseases. On the suggestion of Professor Matthew Hay, M.D. Edin., city medical officer of health, the Aberdeen Town Council has remitted to its public health committee to report as to the town council taking the initiative for providing a sanatorium or hospital for the treatment of cases of phthisis. Professor Hay reports that the epidemic of measles in Aberdeen attained "leviathan" proportions in January of this year, when 1647 cases were reported or discovered, but although school attendance was greatly interfered with the mortality was exceptionally low, there being only 25 deaths. Typhoid fever is rapidly declining. Last week 628 cases in all of zymotic diseases were recorded.

Feb. 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Intermediate Education Commission.

Dr. Lombe Atthill and Sir William Thomson were examined before the Commissioners on Feb. 18th, the Lord Chief Baron filling the chair. Dr. Atthill said that he had been deputed on the part of the Royal College of Physicians of Ireland to ask that the examination of the standard required by the General Medical Council should be held not less than twice a year and if possible three times; moreover, that these examinations should be open to all candidates between the ages of 16 and 40 years. Sir William Thomson said the chief difficulty was in the fact that only one examination in the year was at present provided, though the General Medical Council accepted the junior certificate of the intermediate board as it stands.

Royal College of Surgeons in Ireland.

No less than 10 candidates for the primary grade of the Fellowship examination presented themselves on Feb. 20th.

The Open-air Treatment of Phthisis.

The public at Belfast are being educated as to the open-air treatment of phthisis in a very up-to-date manner, for on Feb. 20th a concert was given in Belfast (the Lord Mayor presiding) in aid of the expenses for the provision of shelters, &c., at the Forster Green Consumption Hospital, and the entertainment was varied by a series of limelight views of the open-air treatment at Nordrach, Falkenstein, Davos, Cromer, Bournemouth, and Belfast. A layman gave a description of the pictures and of the methods employed. There are at present 36 patients in the Fortbreda Consumption Hospital. They have there arranged to construct a verandah and the authorities of that institution are appealing to the public of Belfast to supply the necessary funds for shelters, each of which, it is estimated, will cost about £36.

Changes in Dundalk Poor-law Union.

The Local Government Board have sent down a sealed order in which, in opposition to the repeated expression of opinion of the board of guardians and the Dispensary Committee, the Louth Dispensary District is wiped out and its area divided between the adjacent districts of Dromiskin and Barronstown. The new Dromiskin District is about 10 miles from end to end and the people feel that the poor cannot be attended nearly so well as under the old dispensary system.

The Royal Medical Benevolent Fund.

Dr. Richard Purdon, the honorary secretary and treasurer of the Belfast and District Branch of the above fund, has sent out to all members of the profession an urgent appeal by order of the local committee urging the claims of the society. It is a pity that last year there were 118 members of the medical profession in Belfast and 113 in the country who have never subscribed anything to this, the only charity in connexion with the medical profession in Ireland, while, on the other hand, the central committee of the society gave last year £90 to the widows and orphans of deceased medical men. It is a fact, however much one may deplore it, that this society has never exactly "caught on" in Belfast and some members of the profession in Ulster think that if the society was a purely local one and freed from all centralisation in Dublin it might be more popular. The whole tendency of the day is towards decentralisation and this has its influence on medical matters as well as in affairs of State.

Gas Poisoning.

In a memoranda handed in by the Belfast coroner at a meeting of the Finance Committee of the corporation an important report appears from Dr. J. Lorrain Smith on the recent cases of gas-poisoning in Belfast. In this Dr. Smith says that the cases bring out conclusively for the first time on record the extreme importance of the secondary effects of gas-poisoning. The analysis shows that the amount of gas in the blood of one of the cases (a child) when death occurred was negligible and that death was due entirely to the effects on the heart and nervous system. These analyses will be published in full by Dr. Smith in the medical journals to direct the attention of medical men who may be called to treat such cases to this aspect of gas-poisoning. The blood of another case (a woman, aged 70 years) showed the pink tint of carbon monoxide hæmoglobin. On analysis by the carmine method it was found to be 57 per cent. saturated. The blood of one child, aged four years, was very slightly tinted and was not more than 5 per cent. saturated. Since the child was exposed to the same atmosphere as the adult it is clear that her blood was, at one time at least, as highly saturated as 57 per cent. The artificial respiration which was applied by the medical attendant sufficed to clear the carbon monoxide out of the blood. The child therefore died from what may be called secondary effects of gas-poisoning on the heart and nervous system in spite of the treatment by stimulants applied by the medical man. These researches of Dr. Lorrain Smith when fully published will be of the utmost importance both as to the effects and the best methods of treatment of gas-poisoning which since the introduction of the new "water gas" process is becoming so frequent.

The late Dr. W. C. Townsend.

At a general meeting of the medical profession of the city of Cork, held in the rooms of the Medical and Surgical Association, 118, Patrick-street, on Feb. 18th, it was proposed and carried unanimously:—

> That we beg to record our sorrow at the decease of Dr. William C. Townsend who filled a conspicuous, honourable, and successful position in our profession for over 50 years, and that we express our deep sympathy with all the members of his family in their sad bereavement.

Feb. 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Death of M. Félix Faure.

THE newspapers have of course been full of articles dealing with the death of the late President. One portion of the public which always considers that there must be something out of the common about the death of those in high places will not allow that the death was a natural one. They call to mind the fact that the President was not at the Elysée all the afternoon of his last day and that when he came back at six o'clock in the evening he complained of being in great pain. Others consider it remarkable that after the apoplectic stroke had taken place the President should have been quite clear both in his mind and his speech so that he conversed with those around him for at least half an hour before the end came. It is considered a very serious point that the embalming took place with extreme hurry—i.e., within 12 hours after death—so that any examination from a toxicological point of view was made impossible, supposing such had been called for by public opinion. The embalming, too, was carried out not by a professional embalmer, but by a medical friend who was also a relative of the President's son-in-law. To put an end to all these rumours a formal statement has been issued bearing the signatures of all the medical men who were present during the last moments of the President. These were Professor Potain, Professor Lannelongue, Dr. Bergeron of the Academy of Medicine, Dr. Cheurlot, and Dr. Humbert. In this statement the medical men certify that they were present from the very beginning of those symptoms which in the space of a few hours brought about a fatal termination. They also certify that they all recognised all the symptoms of a rapidly fatal cerebral hæmorrhage accompanied by facial paralysis and left hemiplegia.

A New Method of Purifying Air.

Your readers are already in possession of some of the facts relative to this matter dealing with the researches of M. Laborde and M. Jaubert.[1] At the meeting of the Academy of Sciences held on Feb. 6th, M. Degrez and M. Balthazard read a paper on the use of sodium peroxide in the purification of air. This substance in the presence of water decomposes into sodium hydrate, oxygen, and peroxide of hydrogen. Accordingly M. Degrez and M. Balthazard conceived the idea of utilising for purposes of respiration not only the oxygen, but also the alkali which is produced together with the oxygen. If an animal is supplied with oxygen by means of sodium peroxide the decomposition of this substance produces more alkali than the equivalent necessary to absorb all the carbon dioxide elaborated. If a guinea-pig be placed under a bell-jar made air-tight and supplied with oxygen by means of sodium peroxide it will be found to be perfectly well at the end of four hours, while a control guinea-pig placed in a bell-jar similarly sealed but without the sodium dioxide will die asphyxiated at the end of two hours. The amount of watery vapour in the air expired by the animal is quite enough to bring about the reaction. The sodium peroxide is only attacked very superficially under such conditions and the survival of animals in this test is to be explained rather by the absorption of the carbon dioxide than by a sufficient supply of oxygen.

The Deceptive Remissions of Appendicitis.

At the discussion recently held on the subject of appendicitis at the Academy of Medicine M. Dieulafoy read a paper of which the following conclusions are the pith. 1. The acute symptoms of appendicitis—the abdominal pain, the vomiting and the pyrexia—are sometimes followed by a marked remission, the pain disappearing, the temperature falling, and the patient feeling much better. 2. This remission and defervescence are not always significant of a real improvement in the condition; sometimes they mark a false remission, a deceitful and treacherous calm. 3. It is important to note that this deceptive calm often coincides with the occurrence of very grave lesions, such as gangrene of the appendix, septic infection of the peritoneum, and diffuse peritonitis. 4. The remissions are never complete, for if the case be closely observed it will be seen that the course of events differs from a real improvement by the persistence of some of the symptoms. Thus the abdomen remains tympanitic, the muscular rigidity continues, and the quick pulse-rate persists although the temperature falls. Urobilinuria and albuminuria are by no means uncommon. 5. Such deceptive remissions are sometimes brought about by drugs, especially by the use of morphia or the application of ice bags which mask the onset of danger signal symptoms. 6. This deceptive remission supervenes at various times from as early as the second day to as late as the fourth or sixth days. 7. Such remissions, coinciding as they do with the onset of the gravest peritoneal lesions, show once more the inaccuracy of drawing a sharply defined line between the condition of appendicitis and that of peritonitis. Such views give rise to the most serious errors, for the symptoms of appendicitis and peritonitis are very similar—are, in fact, so interwoven and bound up together that it is impossible to say at what particular moment peritonitis commences. 8. These deceptive remissions are the most potent cause of death from appendicitis. A temporising physician or surgeon seizes upon one of these intervals of calm as a reason for putting off surgical interference; soon, however, some terrible complication supervenes against which surgery is powerless and the patient dies. 9. It is of the first importance to distrust these treacherous calms, to remember their existence, and to operate without delay if it is desired to save the patient from death.

(FROM OUR OWN CORRESPONDENT.)

The Relations between the Stomach and Drugs.

AN interesting study of the relations between the stomach and chemical compounds has been published in the *Münchener Medicinische Wochenschrift*. The stomach, it is pointed out, is liable to be injured by certain drugs whilst other chemical substances are altered by the gastric juice. The absorbing power of the stomach being very limited compared with that of the intestines it is desirable to make a drug pass as quickly as possible from the stomach into the intestines if it is to be absorbed within a short time. Pure water leaves the stomach more quickly than other substances; 500 grammes (17½ fluid ounces) of water leave the stomach within half an hour and 200 grammes within 15 minutes. The gastric juice is not increased by it. Other fluids, such as acid solutions, soup, milk, beer, and especially oil, remain much longer in the stomach and make the gastric juice increase. Water taken after or together with solid food leaves the stomach more slowly than when taken on an empty stomach. If these facts are applied to the administration of drugs it will be found that they leave the stomach in the following order: first when given on an empty stomach with water; then with soup, milk, or oil; then with water after meals; and, finally, without any fluid after meals. These facts were verified by experiments performed with salicylate of soda, iodide of potassium, and charcoal powder. Therefore if a quick absorption and a strong action of a remedy are desired it must be given with water on an empty stomach. A narcotic, antipyretic, or antineuralgic remedy given in this way will act more powerfully than when taken after meals. It has for a long time been known empirically that a given quantity of either beer or wine is more intoxicating when taken on an empty stomach than when taken after food. Another important question is that of the precautions which have to be taken in order that the stomach may not be injured by the administration of drugs. Some medicines, for instance, may be given by the rectum. Certain drugs which are insoluble in the gastric juice are dissolved in the intestines by the pancreatic fluid. This is the case with salol, tannalbin, dermatol, &c. Professor Unna has suggested the giving of drugs in the form of pills coated with a substance soluble in the intestines only; substances of this kind are keratin and the glutoid capsules invented by Professor Sahli. Mucilaginous substances, such as salep, water-gruel, &c., are empirically known to be very bland for the stomach; it is therefore advisable to use them as vehicles for the administration of irritating medicaments. The best way, however, to spare the stomach is to cause the drugs to pass as quickly as possible into the intestines as explained above. All these statements apply only to a stomach the motor function of which is normal; in gastric atony or in pyloric stenosis no medicines must be given by the stomach, but only by the rectum or subcutaneously. As alcohol has been found to increase absorption by the stomach alcoholic solutions may be useful where the rectal or subcutaneous methods are not available.

Argil as a Dressing for Wounds.

Argil is an earthy or clayey product which was largely used in ancient surgery and has again been recommended for the dressing of wounds. Dr. Stumpf of Werneck states in the *Münchener Medicinische Wochenschrift* that it has a strong deodorising and desiccating action and is therefore valuable for the dressing of ulcers with copious fœtid discharge. It has also been found to answer very well as a dressing for recent wounds, for under it they healed without any reaction. Dead bodies could be preserved by putting them in argil dried by heat. The above statements have been verified by Dr. Langemak of the Kaiserswerth Hospital, who points out that argil has several advantages compared with other powders used for dressing. It is very cheap, the price being 10 pfennigs for 500 grammes or about 1½*d.* a pound; it is harmless, so that it may be used in unlimited quantity; and it is not irritating. Its deodorising power is very remarkable and its desiccating action is so strong that crusts are sometimes formed which retard the process of healing. In this case the application of argil ointment is advisable. In eczema a paste composed of argil, glycerine, and vaseline has proved useful.

Chancre on the Sole of the Foot.

At a recent meeting of the Berlin Medical Society Professor Lesser showed a woman, 28 years of age, suffering from a primary chancre on the sole of the foot. In October she was troubled with itching of the sole so that she could not refrain from scratching it. In November a small ulcer made its appearance and in December two large holes formed. On Jan. 4th symptoms of general syphilis were recognised and she was accordingly admitted into the Charité Hospital under the care of Professor Lesser. At that time there was recent roseola over the whole body, together with a papular eruption of the vulva and the anus, and general glandular enlargement especially of the right femoral and inguinal glands. The ulceration of the sole, extending to the fourth and fifth toes, was so deep that the tendons were visible. There was a reddish watery discharge accompanied by only a small amount of suppuration. Another ulcer of somewhat smaller size was found on the plantar side of the great toes. As the roseolar eruption was not preceded by any other ulceration there is little doubt but that this had been a primary chancre. The mode of infection could not be ascertained. The patient being a laundress had sometimes to work among the linen of sick persons. She may perhaps have got some particles of syphilitic virus from the linen on her finger-nails and by scratching may have conveyed the virus to the sole of the foot. Only four cases of primary chancre of the sole of the foot have hitherto been recorded in medical literature.

Feb. 20th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Misericordia.

WHEN the "Romance of Outdoor Relief" comes to be written it will owe some of its most touching, most picturesque, chapters to the Misericordia—a brotherhood peculiar to Tuscany, seen at its best in Florence, though also admirably *en évidence* at Siena, Pisa, Leghorn, and Lucca, and not unworthily represented in the minor provincial towns, inland or maritime. Ecclesiastical in origin, it was founded in 1244 by Pietro di Luca Borsi and its *personnel* is drawn from every social rank, all and individually bound to serve whenever summoned, without fee or reward. The Grand Duke himself, when presiding at a State banquet in the Pitti Palace, has had to rise and leave his guests when his turn came and to bear a hand with tradesmen, nobles, mechanics, professional men—with the company, in fact, promiscuously improvised to transport to hospital some victim of an accident or to carry a patient from the sick bed to the suburban lodging indicated by the physician. The service is not one of "unskilled labour." The members of the brotherhood have all been previously trained to lift the sufferer from the street, to turn the patient in bed, and put him on the "bara" or stretcher with the minimum of pain or of risk to compromised limbs or organs, and thereafter to bear him through the thoroughfares to his destination with the least possible vibration, friction, or disturbance. As often happens, the particular company told off on sudden duty is composed of men as various in altitude as they are in social position, so that in carrying the "bara" shoulder high they employ for the first part of the journey those of them who are as nearly as possible of the same height, and when these are tired they lower their burden to the less tall without interruption of movement or alteration of pace and so continue the shifting process till the sufferer is at his journey's end and laid down in bed with scarcely the consciousness of having been transported at all. Few sights or sounds are more impressive in the Florence of to-day than the "measured march" of the Misericordia through its crowded streets, as robed in black gowns and hooded in black cowls with openings for the eyes the brotherhood wends its way with its burden, the bystander lifting his hat sympathetically, the traffic reverently falling aside, and the street noises subdued to a momentary hush in presence of

> "The still, sad music of humanity."

Queen Victoria, it is well known, took profound interest in the Misericordia during her successive sojourns in Florence, and one of its highest office-bearers, the late Cavaliere Cesare Barsi, was deputed by the Arci-Confraternità to visit the Villa Palmieri, there to set forth to Her Majesty its origin and constitution, the nature of its service, the resources at its command, and the more striking incidents in its experience. As I have said, the brotherhood is peculiar to Tuscany, though other cities have their equivalents, each in its own way rendering similar service; few if any of them, however, being able to point to the same antiquity of origin, to the same large resources, or to the same admirable discipline and organisation. I have been led to give this brief notice of the Misericordia from the funeral obsequies just celebrated in Florence of the Provveditore (or general provider and administrator) of the Brotherhood, Signor Giuseppe Bronzuoli—a singularly imposing and picturesque pageant composed of 300 members of the Arci-Confraternità, 50 "capi di guardia" (chiefs of the guard) and 35 priests. The procession included many citizens among whom were not a few surgeons and physicians, those of them who immediately followed the hearse bearing lighted torches.

"How Study is Rewarded in Italy."

Under this title ("Come si premia lo Studio in Italia") the organ of the ex-Premier, the Marchese di Rudini, comments bitterly on the "struggle for existence" maintained by science in general and medicine in particular in the Italian kingdom. Learned bodies and associations are not lacking, but (says the journal referred to, the *Opinione*) they are *either closed to the young investigator or are miserably* short of funds. When an able and accomplished nature-student has in the course of prolonged research alighted on some pregnant fact or struck out a promising line of discovery he gets no help from these institutions and is reduced to this dilemma—either to pay out of his own purse for the publication of his "findings" or if he is poor to let them lie dormant and (as often as not) see another get the start of him in giving them to the world. The *Opinione* proceeds to adduce a concrete instance. A young Italian nature-student four years ago completed an original series of investigations unique in value scientifically and practically. Not being rich enough to provide the illustrated plates which had to accompany his exposition he had to suspend publication entirely, a request for aid addressed to the Department of Public Instruction being met with the stereotyped "non possumus." All he could do to obviate being anticipated by contemporaries was to send to a periodical a "cenno sommario," as the *Opinione* calls it, of what he had discovered. This "cenno," continues the Roman journal, "fell under the eyes of a distinguished British anatomist who urged the author, unknown to him as he was, to publish his investigations *in extenso*. The author frankly communicated his story to the British anatomist, who immediately sent him a handsome donation of money, and when the work was in this way put into proper shape submitted it to the Royal Society of London which shortly published it. Thus," adds the *Opinione*, "the researches of the young Italian nature-student have at length seen the light in Italy, written in Italian, and illustrated by magnificent plates, only through the private subsidy of a learned Briton and through the intervention of a foreign society! In what country except Italy, it asks, does such an incident occur? Germany fits out scientific commissions and sends them all the world over to study malaria. We," adds the *Opinione* sardonically, "religiously preserve malaria and pellagra for our posterity to suffer from and for our foreign neighbours to study." Our contemporary's theme has, indeed, been often handled in these columns and we can well understand the mortification with which Italians apply to themselves the bitter saying of their great satirist, that among the stings of poverty there is none more galling than that it makes its victim ridiculous in the eyes of the world:

"Nil habet infelix paupertas durius in se,
Quam quod ridiculos homines facit."

Feb. 18th.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In February the following candidates passed in the subjects indicated:—

Surgery.—A. E. Malaher, St. Thomas's Hospital; R. R. Mowll (Section II.), King's College Hospital; C. A. O. Salmon, Guy's Hospital; E. C. Thomas, London Hospital; and R. Le G. Worsley (Section I.), St. George's Hospital and Durham University.

Medicine.—P. A. Chillcott, London Hospital; C. J. Coleman, Cambridge University and Birmingham; F. Dengler (Sections I. and II.), Munich; J. Gallagher, Bombay; E. MacD. Judge, Guy's Hospital; L. Lehmann, Strassburg and Leipsic; R. R. Mowll (Section II.), King's College Hospital; B. J. Nolan, Dublin; E. C. Thomas, London Hospital; and D. O. Williams, Leeds.

Forensic Medicine.—P. A. Chillcott, London Hospital; C. J. Coleman, Cambridge University and Birmingham; H. Cooper, Aberdeen; F. Dengler, Munich; J. Gallagher, Bombay; E. S. Johnson, St. Mary's Hospital; E. MacD. Judge, Guy's Hospital; L. Lehmann, Strassburg and Leipsic; P. Power, Cork and Edinburgh; S. A. Rowley, Bristol; E. C. Thomas, London Hospital; and D. O. Williams, Leeds.

Midwifery.—H. Clough, Leeds; H. Cooper, Aberdeen; F. Dengler, Munich; J. Gallagher, Bombay; E. S. Johnson, St. Mary's Hospital; V. S. Partridge, Charing Cross Hospital; J. W. Robertson, Kingston, Ontario; S. A. Rowley, Bristol; E. C. Scarlett, Royal Free Hospital; A. E. Shaw, Cambridge University and St. Thomas's Hospital; A. Y. St. Leger, Cambridge University and St. Mary's Hospital; E. C. Thomas, London Hospital; J. M. Twentyman, Cambridge University and King's College Hospital; D. O. Williams, Leeds; T. R. Wilshaw, Birmingham; and E. D. Wortley, St. Bartholomew's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—Messrs. H. Clough, E. MacD. Judge, R. R. Mowll, A. E. Shaw, and E. C. Thomas.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau*: Dr. Walther Kuemmel has been appointed Extraordinary Professor of Laryngology and Otology. *Cracow*: Dr. Odo Bujwid has been promoted to the chair of Bacteriology. *Gratz*: Dr. W. Prausnitz has been promoted to the chair of Hygiene. *Liége*: The new bacteriological institute has been publicly opened. *Naples*: Dr. G. Jacontini has been recognised as *privat-docent* of Medical Pathology. *Pavia*: Dr. Silva has been appointed to the chair of Medical Pathology; Dr. Rocci of Turin has been recognised as *privat-docent* of the same subject. *Prague (Bohemian University)*: Dr. Gustav Kunkel has been promoted to the chair of Hygiene.

UNIVERSITY OF BRUSSELS.—At the February examination the following practitioners were successful and obtained the M.D. degree:—John Q. Bown, Ashford; Charles Franks, Newark; W. J. Jenner, London; M. J. Morgan, Aberystwyth; Goone Tillike, Ceylon. There were 12 candidates, seven of whom failed.

DEATH-RATE OF DEVONPORT, PLYMOUTH, AND STONEHOUSE.—The death-rate in the above three towns during 1898 was at the rate of 17·4, 19·6, and 23·1 per 1000 respectively, the birth-rate being 30·4, 29·7, and 30·0 per 1000. The zymotic death-rate was 1·6 per 1000 in Devonport, 2·14 per 1000 in Plymouth, and 3·3 per 1000 in Stonehouse.

HOMŒOPATHIC VACCINATION.—In the course of his annual report Mr. Leah, the medical officer of health of Stonehouse, draws attention to the danger of inefficient vaccination which evades the law and gives no protection to the children. Mr. Leah adds that instead of making four scarifications the practice of the Homœopathic Hospital is to make only one puncture.

ROYAL EAR HOSPITAL.—A successful chamber concert was held at the King's Hall, Holborn, on Feb. 16th in aid of the new building fund of this hospital, the site of which has already been purchased. The hall was well filled and the following artistes volunteered and gave their services: Signor Carlo Ducci, Mr. C. Hayden-Coffin, Mr. Frank Bartlett, Mr. Hulbert Fulkerson, Madame Clara Dowle, Miss Mary Pearson, Miss Florence Lancaster, Miss Marie Bellas, Miss Beatrice Willey, and the Liedertafel quartette.

OPPOSITION TO THE VACCINATION ACT, 1898.—At the meeting of the St. Thomas's (Exeter) Board of Guardians held on Feb. 17th it was reported that Lord Poltimore had written stating that he had presented to the House of Lords the petition of the board in favour of the repeal of the Vaccination Act and his lordship added that he quite agreed with the guardians. Sir Stafford Northcote stated that he had presented a similar petition to the House of Commons and Mr. Seale-Hayne, M.P., wrote saying that he did not support the Vaccination Act of 1898, but until something had happened to give severe proof of its ill-effects it was premature to hope for further legislation on the subject in which sentiment appeared to be a more potent factor than reason.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—A meeting of this association was held on Feb. 17th, at the Conjoint Examination Hall, Victoria-embankment, when Captain P. W. O'Gorman, D.P.H., Indian Medical Service, read a paper on the Scientific Valuation of Alcohol in Health. Dr. Morton presided in the absence of the President, Professor Sims Woodhead, through illness. The conclusions of the lecturer were that alcohol did not act as a food, that it did not retard waste but was a protoplasmic or tissue poison, that it did not impart energy but was essentially a nerve paralyser, that it was dangerous both in hot and cold climates, and that it did not conduce to longevity. He pointed out that it reduced vascular tension and that Dr. Martin had shown that the strength of the heart contraction was diminished by alcohol. Dr. Ridge, in moving a vote of thanks to the lecturer, said that he hoped the paper would be published as he had found many medical men entirely ignorant of the immense number of facts which had accumulated proving the harm done by alcohol even in moderate doses and the advantages of total abstinence; these things were not taught in the usual way, but there was some hope for the future as there were between 300 and 400 medical students who were abstainers and belonged to the association. The vote was seconded by Dr. Claude Taylor and carried unanimously.

ROYAL COLLEGE OF SURGEONS IN IRELAND—DENTAL EXAMINATION.—The following gentlemen, having passed the necessary examination, have been admitted Licentiates in Dental Surgery of the College: Mr. A. T. Green (Belper, Derbyshire) and Mr. D. Saville (Leeds).

ACCIDENT TO A MEDICAL MAN.—On Feb. 14th Mr. R. Griffith, L.R.C.P., L.R.C.S. Edin., of Glyn Neath, Glamorganshire, was thrown from his horse and received a severe wound of the head with concussion of the brain.

MEDICAL MAGISTRATE.—Mr. J. R. Hughes, M.D. Edin., M.R.C.S. Eng., of Denbigh, coroner for West Denbighshire, has been appointed a magistrate for the borough of Denbigh.

THE RIGHTS OF MEDICAL MEN.—The Gosport magistrates have dismissed a police summons against a medical man who rode a bicycle on the footpath on the ground that a practitioner called to an urgent case has a legal right to take the shortest way.

THE Aylesbury Dairy Company have issued a circular entitled "Milk in Relation to Tuberculosis and other Diseases," which is designed to remove any anxiety in this connexion which may be present in the minds of their customers. The circular states briefly the precautions by medical inspection and regular analysis taken to ensure that only pure milk, free from all germs of disease and from adulteration, is supplied.

UNIVERSITY OF CAMBRIDGE.—At the congregation held on Feb. 16th the plans for the erection of the Sedgwick Memorial Museum, towards which £27,000 have been subscribed, were approved by the Senate. Mr. A. W. Hill of King's College has been appointed Demonstrator of Botany for five years. The degrees of M.B. and B.C. have been conferred on Mr. C. Powell, B.A., of Emmanuel College.

BOARDS OF GUARDIANS AND VACCINATION.—The Wellingborough Board of Guardians have failed to appoint a vaccination officer for the Higham Ferrers District and the Local Government Board has intimated that if this action is persisted in it will apply for a *mandamus*. The Board of Guardians, by a majority of six votes, determined to adhere to the resolution on the books. All the lady guardians voted for this course. All the clergy present except one voted against it.

THE CANCER HOSPITAL, BROMPTON.—The annual meeting of the governors of this charity was held in the board room of the hospital recently, Sir George S. Measom presiding. From the report of the committee it appeared that during the past year 2477 new patients were received, 835 being in- and 1642 out-patients, whilst the total number of attendances of out-patients was 13,803. Much regret was expressed at the untimely deaths of Mr. W. H. Hughes, secretary, and Mr. Edward Cotterell, an able and valued surgeon of the hospital for the past six years. The committee in their report regret that there has been a considerable falling off in donations and annual subscriptions during the past year. Mr. Fred W. Howell, of the York County Hospital, has been elected to the office of secretary, and Mr. C. Jarman has been appointed as assistant secretary of the hospital in appreciation of his services for 26 years. The meeting terminated with the usual votes of thanks.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Conscientious Objector.

ON Friday, Feb. 17th, Mr. BOULNOIS introduced into the House of Commons a Bill to repeal Section 2 (the conscientious objector section) of the Vaccination Act of last year. The hon. Member has put down the Bill for second reading on Wednesday, March 1st, when, however, there is little chance of it being reached having regard to the number and character of the measures in front of it.

Seats for Shop Assistants.

MR. SOUTTAR has introduced into the House of Commons a Bill to provide for seats being supplied for the use of shop assistants in Scotland.

The Law of Murder.

MR. W. AMBROSE has introduced into the House of Commons a Bill to amend the law of murder with reference to the doctrine of constructive criminal malice.

HOUSE OF COMMONS.

THURSDAY, FEB. 16TH.

The London Water Commission.

Mr. BALFOUR, in reply to Mr. James Stuart, said he was informed by the Chairman that the Royal Commissioners on the London Water question were at present unable to fix any date for the presentation of their second report, but there would be as little delay as possible after the taking of evidence was concluded.

Immoral Advertisements.

Mr. JOHN ELLIS asked the Home Secretary whether his attention had been directed to the case of three men of the name of Chrimes who were on Dec. 20th, 1898, sentenced to seven and 12 years' penal servitude for a widespread conspiracy to charge persons with having committed crimes with intent to extort money; whether the following rider of the jury had come under his notice: "The jury feel that such a vile plot even with all the ingenuity displayed in it, could only have been possible by the acceptance of such immoral advertisements by a section of the press, religious and secular, well knowing their nature. They further expressed their earnest conviction that means should be taken to suppress such advertisements and the institution from which they emanate, as they consider them direct incentives to ignorant and evil-minded women to commit crime"; and whether he saw his way to take any steps in the direction indicated.—Sir MATTHEW WHITE RIDLEY said: My attention has been called to this case and to the rider of the jury. In my opinion the question of dealing with indecent advertisements, either by amending the Indecent Advertisements Act or otherwise, is one deserving of serious consideration and I am giving my best attention to the subject.

Vaccination in the Civil Service.

Mr. BARTLEY asked the Secretary to the Treasury whether vaccination was required of all civil servants, including those young persons and others who are temporarily employed in the Post Office and other departments.—Mr. HANBURY said: All candidates for admission to the permanent Civil Service and all established workmen in the civil departments must show that they have been satisfactorily vaccinated, otherwise revaccination is required. Customs boatmen must have been vaccinated within seven years. In the case of persons temporarily employed each department is at liberty to fix its own requirements. In the Post Office service evidence of both primary and secondary vaccination is required before employment, whether permanent or temporary, and revaccination must have taken place within the preceding seven years. The only exceptions are (1) soldier candidates, in whose case vaccination is presumed, (2) sub-postmasters, and (3) persons casually employed for short periods.—Mr. JAMES LOWTHER: Are conscientious objections entertained?—Mr. HANBURY: I think not.

Hospital Provision for the Khartoum Expedition.

Captain NORTON asked the Under Secretary of State for War whether he could state if an application was made by the army medical authorities for a hospital ship in connexion with the Khartoum Expedition in sufficient time for it to have reached Alexandria before the arrival of the sick from the front.—Mr. WYNDHAM said that an application for a hospital ship was made by the principal medical officer in Egypt to the general officer commanding the army of occupation on June 27th. Both these officers were at that time in London. The general officer commanding sent forward the application unofficially, adding that if on arrival in Egypt he found it necessary he would again apply through Lord Cromer. Pending the receipt of such an official application the general officer commanding was given full powers to take up passages for the sick and wounded, together with their medical attendants, nurses, &c., on board the P. and O. and other passenger ships passing almost daily through the Suez Canal, supplementing in this manner the accommodation afforded by the two Government transports allotted to this service. On Sept. 14th the general officer commanding applied officially by telegraph for a hospital ship, but since it would have taken five weeks to fit out and transfer such a ship to Alexandria it was decided to adhere to the arrangements already made. 465 invalids were conveyed by six vessels between Sept. 20th and Oct. 30th and all arrived in England considerably sooner than would have been the case had a hospital ship been despatched.—Captain NORTON asked whether, in consequence, 60 or 70 officers and men were down in hospital at Alexandria with only two nurses to attend to them?—Mr. WYNDHAM: No complaint to that effect has reached us. But if what is alleged occurred it was not due to the non-employment of a special hospital ship. It may have been due to the accommodation at Cairo and Alexandria not being sufficient for an outbreak of enteric fever which took place during the end of the campaign.—Captain NORTON asked if the hon. gentleman would inquire why the wounded coming down from the front were not properly provided for.—No answer was given to this question.

Venereal Disease in the Army in India.

Major RASCH asked the Secretary of State for India whether he was aware that out of an actual strength of 16,600 British troops proceeding on service in the recent campaign on the North-west frontier 1500, or nearly 10 per cent., were incapacitated for service in the field by venereal disease, and whether the Government of India proposed to take any further steps to remedy this condition of affairs.—Lord GEORGE HAMILTON replied that the force from which the 16,600 British troops were drawn for service in the recent campaign consisted of 21,439 men. Of these 939 were rejected as unfit for service on account of venereal disease, while a further number of 492 were incapacitated during the campaign for the same reason. The total number of men known to have been thus disqualified for active service was therefore 1421, or nearly 7 per cent. on a total strength of 21,439. The Government of India were fully aware of the importance of this matter and had taken and were taking steps with the object of diminishing the prevalence of venereal disease am[illegible] country.

Vaccination in the Peabody Buildings.

Mr. Lough asked the Home Secretary whether his attention had been drawn to the fact that large numbers of the tenants in the buildings of the Peabody Trust in London had received notice to quit unless their children were vaccinated; and whether he would use his influence with the trustees to secure from them the same respect for the conscientious convictions of their tenants as was generally extended by the proposals in the Government Bill of last year.—Sir Matthew White Ridley replied: I was not aware of the incidents to which the hon. Member alludes but I think that it is a case in which it would be clearly improper for me to interfere.

Condition of the Underground Railways in London.

Mr. R. G. Webster asked the President of the Board of Trade whether his attention had been called to the discomfort travellers on those metropolitan underground railways worked by steam power had to suffer owing to the prevalence of noxious gases and sulphurous coal smoke; and if the companies could be compelled, by legislation or otherwise, to mitigate this nuisance to the travelling public.—Mr. Ritchie replied: In 1897 I appointed a committee to inquire into the system of ventilation of the tunnels of the Metropolitan Railway and the report of the committee and minutes of evidence were presented to this House in the same year. As recently as December last the managing director of the Metropolitan Railway informed the Board of Trade that the directors of that company, conjointly with the District Company, had secured the services of Sir J. Wolfe Barry and Mr. W. H. Preece, and instructed them to provide the necessary electric plant and appliances for the equipment of a section of the line for experimental working. I hope that these experiments may result in the adoption of some system of electric traction.

The Small-pox Epidemic in Middlesbrough.

Mr. Chaplin, in reply to Mr. Pickersgill, said that no inquiry in the ordinary sense of the term was made by the *Local Government Board* into the outbreak of small-pox in Middlesbrough in November, 1897—June, 1898, but when the disease began to spread a medical inspector was sent there by the Board to advise as to the best means of controlling the disease and of preventing its spread within the borough and to the neighbouring districts. No formal report was made to the Board, though they were furnished from time to time with memoranda as to the progress of the disease and the means of prevention that were being adopted. Under these circumstances the Board did not propose to issue any report on the outbreak, but he might mention that the Middlesbrough medical officer of health in July last issued a special report on vaccination and its relation to the recent epidemic of small-pox.

FRIDAY, FEB. 17TH.

Foreign Milk.

Mr. Warner asked the President of the Local Government Board if the Local Government Board could do anything to impose the same sanitary restrictions on foreign milk as are applied to British milk.—Mr. Chaplin replied: Foreign milk, as soon as it is imported, is subject to the same treatment as English milk. But the regulations which apply to dairies and cowsheds in this country generally and to the protection of milk therein cannot, of course, apply to dairies or cowsheds abroad. The matter, however, is of comparatively small importance, for while the consumption of milk is estimated at 600,000,000 gallons a year in this country 60,000 gallons only were imported for the ten months up to the end of January last and according to the latest returns the quantity is decreasing as compared with last year.

Tuberculosis in Cattle.

Mr. Warner asked the First Lord of the Treasury if he proposed to introduce any Bill for appointing Government inspectors to inspect and condemn cattle afflicted with tuberculosis, as uniform action all over the country was most desirable on this subject and as one private Bill had been introduced by a corporation to give its own inspectors these powers outside the municipal boundaries.—Mr. Walter Long, President of the Board of Agriculture, answered the question, saying: It is not the intention of the Government to appoint inspectors for the purpose suggested by the hon. gentleman, and as far as the legislation to which he referred is concerned, by which, I presume, he means private Bill legislation, of course those Bills come before the committees upstairs, and it is impossible to say what powers Parliament would grant to local authorities.

MONDAY, FEB. 20TH.

Lead Poisoning in the Potteries.

Mr. Holland asked the Home Secretary whether his attention had been called to the death of Jane Heath, a potters' colour mixer, from epilepsy, on Jan. 2nd last at Burslem, and to the fact that no inquest was held into the cause of her death; and whether he would suggest to the coroner for the district to order an inquest in every case of death where lead poisoning was suspected.—Sir Matthew White Ridley replied that he had made inquiry into this case and found that the death was duly reported to the coroner who, after consultation with the medical practitioner who had attended the deceased, accepted his opinion that death was not attributable to lead poisoning.

Vaccination Certificates.

Mr. Bartley asked the President of the Local Government Board whether anyone could be revaccinated by the public vaccinator free of charge, and whether a certificate of revaccination could be obtained free or at a small fee by anyone who wished for it after revaccination.—Mr. Chaplin replied: Any person who is not less than 10 years of age and has not been previously revaccinated within a period of 10 years may be revaccinated by the public vaccinator free of charge. In such a case it is the duty of the public vaccinator, if so required, to deliver to the person revaccinated a certificate of the result of the operation.

The Royal Army Medical Corps.

Sir Walter Foster asked the Under-Secretary of State for War whether, in view of the fact that the strength of the Royal Army Medical Corps detailed for duty during the late autumn manœuvres—viz., 23 officers and 215 men—was quite inadequate for an army of nearly 48,000 of all ranks and in view of Lord Wolseley's comment thereon that the medical staff requires augmentation, he could state from what source a sufficient number of medical officers, as laid down in mobilisation tables, is to be drawn for the two army corps declared by the Commander-in-Chief to be always ready for embarkation for field service abroad.—Mr. Wyndham replied: The strength of the Royal Army Medical Corps employed at the manœuvres was 68 officers and 312 men and not 23 officers and 215 men as stated in the question. The 224 officers required for two army corps can be provided from existing home establishments. There would be no justification for withdrawing 224 medical officers from their normal duties for manœuvres. In time of war this would be done and the vacancies supplied with civilian practitioners.

Accommodation for Convalescent Soldiers.

Mr. Wyndham replying to a question by Captain Norton said that the Secretary of State for War has decided that accommodation for convalescent soldiers shall be provided in existing barracks at 10 selected stations. There would be room for about 3500 convalescents in all.

Hospital Arrangements in Egypt.

Captain Norton asked the Under Secretary of State for War whether he could state if, upon receipt of the unofficial application for a hospital ship by the general officer commanding the army of occupation in Egypt on June 27th, 1898, any steps were taken to fit out a ship and to hold it in readiness to proceed to Egypt in anticipation of the expected renewed application; what steps, if any, were taken to supplement the existing hospital accommodation and nursing staff at Cairo and Alexandria with a view to the proper care of the sick and wounded while awaiting embarkation; and whether he could state the average number of patients in hospital at Cairo and Alexandria between Sept. 20th and Oct. 30th, 1898, as well as the average number of trained nurses in attendance on them during that period, also the average time that each patient remained at Alexandria or Cairo awaiting embarkation and the number of deaths that took place amongst the patients.—Mr. Wyndham said: No steps were taken to fit out a hospital ship on the receipt of the unofficial communication. The hospital accommodation at Cairo and Alexandria was supplemented by tents pitched close to the hospitals. At Cairo, where the accommodation is greatly in excess of normal peace requirements, the tents were used for a few days only. The average number of patients in hospital during September was: At Cairo, 354; at Alexandria, 113. During October: Cairo, 347; Alexandria, 258. Information has been asked for from Egypt as to the average time during which each patient awaited embarkation. This cannot be ascertained from the returns at the War Office. The deaths between Sept. 20th and Oct. 30th were: At Cairo, 67; at Alexandria, 37. The nursing staff at Cairo and Alexandria was supplemented by the addition of 138 non-commissioned officers and men of the Royal Army Medical Corps.

Births, Marriages, and Deaths.

BIRTHS.

Adams.—On Feb. 15th, the wife of E. Weaver Adams, F.R.C.S., of Slough, of a son.

Barker.—On Feb. 21st, at the Old Brewery House, Watford, the wif of J. C. Barker, M R.C.S., L.R.C.P., of a son.

Batterham.—On Feb. 15th, at Grand-parade, St. Leonards-on-Sea, the wife of J. W. Batterham, M.B., F.R.C.S., of a son.

Campbell.—On Feb. 18th, at Eldon Royd, Bradford, the wife of H. J. Campbell, M.D., F.R.C.P., of a daughter.

Thomas.—On Feb. 18th, at Greenlawn, Pen-y-lan, Cardiff, the wife Mr. J. Lynn Thomas, F.R.C.S., of a daughter.

Thomson.—On Feb. 14th, at Bridge House, Retford, the wife of George Thomson, M.B., C.M. Edin., of a son.

MARRIAGES.

Austen—Sleigh.—On Feb. 14th, at St. Peter's, Brighton, Surgeon Thomas Austen, R.N., of H.M.'s Dockyard, Sheerness, to Ethel Dorothea Sleigh, third daughter of John Sleigh, J.P., late of Eversley, near Matlock, Derbyshire.

Bowes—Lee.—On Feb. 9th, at Christ Church, Herne Bay, T. A. Bowes, M.D., son of John Bowes, M.R.C.S., of Herne Bay, to Gertrude, youngest daughter of George Lee, Herne Bay.

Sadler—Holland.—On Feb. 7th, at the Parish Church, Ashbourne, Ernest A. Sadler, M.D., The Mansion, Ashbourne, to Elizabeth, second daughter of William Richard Holland, St. John's House, Ashbourne.

Shine—Fitzgerald.—On Feb. 14th, at Holy Trinity Church, Brook Green, Kensington, by the Rev. F. Grant, C.C., assisted by Rev. John Hill, P.P., Barnsley, John Power Shine, M.B., B.Ch. R.U.I., to Gretta Apjohn, fourth daughter of John Connell Fitzgerald, Esq., Abington House, Murroe, co. Limerick, Ireland.

Tyson—Du Boulay.—On Feb. 14th, at St. Paul's, Sandgate, William Joseph Tyson, M.D., of Folkestone, to Lola Houssemayne, youngest daughter of Julius Houssemayne du Boulay, Esq., J.P., of West Lawn, Sandgate.

Wingfield—Cole.—On Feb. 14th, at St. John's Church, Boscombe, Hants, Hugh B. Wingfield, M.D. Cantab., of Winchester, to Catharine Jane, youngest daughter of Major-General G. Wynne Cole, H.M. Indian Army.

DEATHS.

Roe.—On Feb. 16th, in London, Edward Roe, M.A. Cantab., L.R.C.P. London, M.R.C.S., of Lyndhurst, Hampshire, aged 53.

Terry.—Feb. 16th, at his residence, 35, Grosvenor, Bath, John Terry, M.R.C.S. Eng., and L.S.A., in the 77th year of his age. For many years proprietor of Bailbrook House Asylum.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat (2 P.M.).

TUESDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1 30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (1st).—St. Bartholomew's (1.30 P.M.), University College, (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond street (9 30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (2nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2 30 P.M.), London Throat (2 P.M.).

FRIDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3 30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2 30 P.M.), West London (2. 30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (4th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (27th).—Medical Society of London.—8.30 P.M. Dr. S Martin: Auto-intoxication and its bearing on the Treatment of Disease.

TUESDAY (28th).—Royal Medical and Chirurgical Society (20 Hanover-square, W.).—8 30 P.M. Paper:—Mr. W. J. Walsham: A Case of Extirpation of a Large Non pulsating Aneurysm, involving the Common, Internal, and External Carotid Arteries of the Right Side of the Neck, with *remarks* on *Non-pulsation* in Aneurysms and the Treatment of Aneurysms by Extirpation.

WEDNESDAY (1st).—Obstetrical Society of London.—8 P.M. Specimens will be shown by Mr. Bland Sutton, Mr. Targett, and others. Mr. A. Doran (President): Inaugural Address. Paper:—Dr. C. H Roberts: A second Case of Primary Carcinoma of the Fallopian Tube.

Society of Arts.—8 P.M. Mr W. P. Rix: Leadless Glazes.

THURSDAY (2nd).—Harveian Society of London (Stafford Rooms, Titchborne-street, Edgware-road).—8.30 P.M. Mr. D'Arcy Power: *On Vanishing Tumours.*—Mr. B. Gardner: *A New Ether Inhaler.*

Neurological Society of London (11, Chandos street, W.).—8.30 P.M. Clinical Evening. Dr. F. E Batten: Muscular Atrophy in a Child.—Dr. T. D. Savill: Epileptiform Seizures of probable Vaso-motor Origin.—Dr H A. Caley: Syringomyelia with Sudden Increase of Symptoms.—Dr. W. Harris: Hæmorrhage into the Spinal Cord (? Syringomyelia).—Dr. J. H. Bryant: Paralysis Agitans following *Typhoid Fever in a Man aged 31 years.*—Dr. Stansfield: Epileptic Insanity associated with Mastoid Disease, Operation, Relief of Mental Symptoms And other cases.

British Balneological and Climatological Society (20, Hanover square, W).—3 30 P.M. Papers:—Dr. D. Kerr (Bath): Treatment of Disease by Heat.—Dr Hedley: The Therapeutics of Heat.

FRIDAY (3rd).—West Kent Medico-Chirurgical Society (Royal Kent Dispensary, Greenwich road, S.E).—8.45 P.M. Clinical Cases:—Dr. McCann and Dr. Ezard Notes with specimens of (1) a Case of Dermoid Cyst of Ovary, simulating Extra-uterine Pregnancy; (2) a Case of *Parovarian* Cyst of Unusual Size.—Mr. *Ernest Clark*: Eye Cases (Living and Pathological).—Dr. Toogood: Cases from Lewisham Infirmary.—Dr. Scholefield: Clinical Cases.

West London Medico-Chirurgical Society (West London Hospital, Hammersmith, W.).—8 15 P.M. Clinical Evening. Cases will be shown by Dr. S. Taylor, Mr. R. Pollock, Mr. McA. Eccles, and others.

Laryngological Society of London (20, *Hanover-square, W.*).—5 P.M. Cases will be shown by the President, Dr. De H. Hall, Mr. Bowlby, Dr. E. Law, Dr. StClair Thomson, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (27th).—Royal College of Surgeons of England.—5 P.M. Mr. B. G. A. Moynihan The Anatomy and Surgery of the Peritoneal Fossæ. (Arris and Gale Lecture.)

The Royal Institute of Public Health (Rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, W.).—8.30 P.M. Prof. J. McFadyean: Tuberculosis in Cattle.

West London Post-Graduate Course (West London Hospital, W.).—5 P.M. Mr. McAdam Eccles: The Application of Trusses and of Abdominal Supports.

TUESDAY (28th).—Royal College of Physicians of London.—5 P.M. Dr. G. V. Poore: The Earth in Relation to the Preservation and Destruction of Contagia. (Milroy Lecture.)

West-end Hospital for Diseases of the Nervous System (73, Welbeck-street, W.).—4 P.M. Dr. D. Grant: Cases of Aural and other forms of Vertigo.

National Hospital for the Paralysed and Epileptic (Bloomsbury).—3 30 P.M. Mr. Gunn: The Value of the Visual Fields in *Diagnosis.*

WEDNESDAY (1st).—Royal College of Surgeons of England.—5 P.M. Mr. B. G. A. Moynihan: The Anatomy and Surgery of the Peritoneal *Fossæ. (Arris and Gale Lecture.)*

Evelina Hospital (Southwark-bridge-road, S E.).—4.30 P.M. Mr. F. C. Abbott: Clinical Demonstration on the Complications of Ear Disease. (Post Graduate Course).

Hospital for Consumption and Diseases of the Chest (Brompton).—4 P.M. Dr. H. Mackenzie: Medicinal Treatment of Pulmonary Tuberculosis.

THURSDAY (2nd).—Royal College of Physicians of London.—5 P.M. Dr. G. V. Poore: The Earth in Relation to the Preservation and Destruction of Contagia. (Milroy Lecture.)

Charing-cross Hospital.—4 P.M. Dr. M. Murray: Demonstration of Medical Cases. (Post-Graduate Class.)

Royal London Ophthalmic Hospital (Moorfields).—8 P.M. Mr. *Tweedy: Diseases of the Conjunctiva, with Special Reference to* their General Pathology and Classification.

London Temperance Hospital.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

The Hospital for Sick Children (Gt. Ormond street, W.C.—4 P.M. Dr. Garrod: Demonstration of Selected Cases.

West London Post-graduate Course (West London Hospital, W.).—5 P.M. Mr. McAdam Eccles: The Application of Trusses and of Abdominal Supports.

St. John's Hospital for Diseases of the Skin (Leicester-square, W.C.).—4.30 P.M. *Dr. M. Dockrell: Cases of Telangiectasis* and Vascular New Growths.

FRIDAY (3rd).—Royal College of Surgeons of England.—5 P.M. *Mr. B. G. A. Moynihan: The Anatomy and Surgery of the* Peritoneal Fossæ. (Arris and Gale Lecture.)

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The *Index to Vol. II. of 1898,* which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in The Lancet of Jan. 7th.

VOLUMES AND CASES.

Volumes for the second half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 6*d.*

To be obtained on application to the Manager, accompanied by remittance.

Communications, Letters, &c., have been received from—

A.—Dr. Atthill, Dublin; Messrs. Armour and Co., Lond.; Messrs. Allen and Hanburys, Lond.; Apollinaris Co., Lond.; A. S. M.; *Australian Journal of Dentistry*, Melbourne, Secretary of; Messrs. Aitken and Co., York; *Archives Provinciales de Médecine*, Paris, Editor of; A. W. B.; Mr. C. Ady, Lond.; Messrs. Arnold and Sons, Lond.; A. J.

B.—Mr. H. Barham, Maidstone; Mr. C. Birchall, Liverpool; Birmingham Hospital for Skin Diseases, Hon. Secretary of; *Bath Herald*, Proprietor of; Mr. J. Barr, Bolton; Messrs. Blake, Sandford, and Blake, Lond.; Messrs. Bates, Hendy, and Co., Reading; Birmingham Tame and Rea District Drainage Board, Engineer of; Messrs. Burgoyne, Burbidges, and Co., Lond.; Dr. T. Beattie, Newcastle-on-Tyne; Mr. W. Bassett, Newport; Messrs. Burroughs, Wellcome, and Co., Lond.; Mr. A. A. Bowlby, Lond.; Mr. E. Burney-Young, Lond.; Messrs. C. Barker and Sons, Lond.

C.—Mr. W. H. Copley, Wisbech; Cortland Wagon Co., Lond.; Mr. T. S. Cotterell, Bath; Dr. H. Campbell, Lond.; Mr. F. G. H. Cooke, Lond.; Messrs. A. H. Cox, Brighton; Cumberland and Westmorland Asylum, Carlisle, Secretary of; Dr. T. Colvin, Glasgow; Mrs. Cousins, Southborough; Mr. H. V. Craster, Larkhall; Mr. A. Chopping, Colchester; Dr. J. J. Cranny, Dublin; Mr. F. W. Clarke, Manchester; Mr. W. F. Clay, Edinburgh; Cancer Hospital, Lond., Secretary of.

D.—Dr. Dingan, Oxford; Mr. H. Drewry, Nottingham; Messrs. Dowie and Marshall, Lond.; Mr. H. G. Dixon, Hoxton; Mr. J. Dawkins, Leamington; Dr. F. Deas, Lond.

E.—Mr. F. Eve, Lond.

F.—Mr. H. R. Faulkner, Lond.; Mr. M. Farrant, jun., Exeter.

G.—Mr. D. Gamble, Ashton-in-Makerfield; Messrs. Grimwade, Ridley, and Co., Lond.; G. W., Chatham.

H.—Dr. E. Harrison, Hull; Mr. C. Higgens, Lond.; Dr. A. B. Harris, Falmouth; Hovis Bread Flour Co., Macclesfield.

J.—Mr. Raymond Johnson, Lond.; J. R. B.; J. H. D.

K.—Dr. P. J. Kolsky, Simpheropol; Mr. C. King, Lond.; Mr. A. F. Stanley Kent, Lond.; Mr. R. Kemp, Lond.

L.—Mr. W. L. Liston, Tewkesbury; Dr. P. W. Latham, Cambridge; Dr. A. P. Luff, Lond.; Mrs. Lemon, Lond.; L. B. W.; Mr. F. W. Lowndes, Liverpool; London Temperance Hospital, Secretary of; Messrs. J. Law and Co., Glasgow; Messrs. Longmans and Co., Lond.

M.—Dr. R. W. MacKenna, Berlin; Messrs. McKenna and Co., Lond.; Mr. J. H. Montague, Lond.; Messrs. J. Maclehose and Sons, Glasgow; Medical Society of Victoria, Melbourne, Hon. Treasurer of; Maltine Manufacturing Co., Lond.; Messrs. Macmillan and Co., Lond.; Manchester Royal Infirmary, Secretary of; Middlesex Hospital, Lond., Secretary of; Comte de Marillac; Mr. E. Morgan, Lond.; Mr. W. Morton, Tamworth.

N.—Messrs. Niblett and Sutherland, Lond.; National Press Cutting Bureau, Lond.; Northern Hospital, Secretary of; National Hospital for Consumption, Ventnor, Secretary of; Dr. David Newman, Glasgow.

O.—Mr. J. Offord, Lond.

P.—Mr. Y. J. Pentland, Edinburgh; Mr. J. E. *Platt, Manchester*; Messrs. T. Padmore and Sons, Birmingham; Mrs. H. Pease, Darlington; Plumbers' Company, Lond.; Mr. F. H. Payne, Lond.

R.—Mr. E. J. Reid, Lond.; Rebman Publishing Co., Lond.; Royal Portsmouth Hospital, Secretary of; Royal Victoria Homes, Bristol, Warden of; Mr. J. Robinson, Kidderminster; Mr. J. W. Rogers-Tillstone, East Malling; Royal College of Surgeons, Dublin, Registrar of; Mr. H. B. Robinson, Lond.; Dr. J. W. Russell, Birmingham; Roxburgh District Asylum, Melrose, Secretary of; Mr. W. Reeve, Lond.

S.—Dr. F. W. Saunders, Lond.; Signor G. Schunnach, Rome; South Devon Hospital, Plymouth, Hon. Secretary of; Mr. Holmes Spicer, Lond.; Miss E. Sellers, Sudbury; Surgical Aid Society, Lond., Secretary of; Mr. R. C. Saunders, Lond.; Society of Apothecaries, Lond., Secretary of; *Singapore Free Press*, Editor of; Messrs. Smith, Elder, and Co., Lond.

T.—Tower House Retreat, Westgate-on-Sea; Dr. H. M. Tickell, Cheltenham; T. T.

V.—Mr. J. W. Vickers, Lond.; Dr. M. A. Veeder, Lyons, N.Y.

W.—Mr. A. L. Whitehead, Leeds. W. *Middlesbrough*; Mr. Edgar Willett, Lond.; Messrs. M. Whitwell, Son, and Judge, Lond.; West Kent General Hospital, Maidstone, Secretary of; Dr. James Wallace, Greenock; Mr. G. H. Wade, Chislehurst; Messrs. Wilcox and *Co., Lond.*; Mr. T. Woods, Gillingham; Dr. Wrangham, Leicester.

Y.—Yost Typewriter Co., Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. J. Althaus, Lond.; Dr. C. M. Allan, Longton; A. M.; Mr. F. C. Allen, Ashton-under-Lyne; Anderson's College Medical School, Glasgow, Secretary of; Dr. F. J. Allen, Birmingham; Mr. J. E. Anderton, New Mills; Mr. G. Awford, Gloucester; A. W. H. L.; A. W. S.

B.—Mr. M. L. Bensusan, Lond.; Birmingham City Asylum, Clerk of; Birkenhead Children's Hospital, Hon. Treasurer of; Belfast District Asylum, Clerk of; Mr. C. S. Bowker, Pontnewydd; Dr. A. Bronner, Bradford; Bootle Borough Hospital, Clerk of; Dr. W. T. Bell, Hayes; Mr. F. Bauermeister, Glasgow; Baxter, Liverpool; Mr. J. C. Barker, Watford; Mrs. E. S. Browett, Coventry.

C.—Mr. H. A. Collins, Saxmundham; Dr. W. H. Corfield, Lond.; Mr. W. P. Cox, Leicester; Dr. S. M. Copeman, Lond.; Mr. W. L. Crowdy, Lond.; Messrs. Cassell and Co., Lond.; Dr. Cane, Peterborough; C. G. A. C.; Mr. A. Clarke, Morley; Mr. T. A. Collinson, Teddington; C. E. W.; County Asylum, Prestwich, Treasurer of; C. J. S.

D.—Mr. J. T. Davenport, Lond.; Mr. G. T. De Fraine, Aylesbury; Messrs. J. Dewar and Sons, Lond.; Messrs. Douglas and Foulis, Edinburgh.

E.—Messrs. J. K. Eve and Son, Bedford.

F.—Dr. Fulton, Eston; Messrs. Fletcher, Fletcher, and Co., Lond.; Miss F., Southborough.

G.—Messrs. R. W. Greeff and Co., Lond.; Great Yarmouth Hospital, Secretary of; G. M. S.; General Apothecaries' Co., Lond.; General Medical Council, Lond.; G. de V. B.

H.—Mr. W. Hardiker, Priors Marston; Mrs. Harvey, Lond.; Mr. S. V. Holgate, Nottingham; Herts County Asylum, St. Albans, Secretary of; Haydock Lodge, Newton-le-Willows; Superintendent of; Hemel Hempstead Sanatorium, Medical Superintendent of; Mr. J. Heywood, Manchester; H. B.; H. C.; H. M., Cambridge; H. F. B.

J.—Mr. J. Jackson, Denholme; Jenner Society, Gloucester, Hon. Secretary of; J. H. A.; J. J. M.; J. McC. M.; J. F. M.; J. H. B.; J. McG.; J. J. F.

K—Dr. W. Knott, Middlesbrough; Messrs. Keith and Co., Edinburgh.

L.—Mr. G. H. Longton, Barford; Mr. C. Lucas, Burwell; London Throat Hospital, Secretary of; London College of Pharmacy; Dr. P. Letters, Valencia Island.

M.—Mr. R. P. Merry, Hemel Hempstead; Mr. W. A. Mushé, Lond.; Medicus, Winfrith; Mr. J. McLintock, Slamannan; M.D., Grantham; Medicus, Wrexham; Medico, Bath; M. H. P.; Dr. J. McNaught, Waterfoot; Mr. D. McIntyre, Dundee; Messrs. Murley Bros., Lond.

O.—Omega.

P.—Dr. E. J. Pritchard, Hinckley; Messrs. Preston Bros. and Co., Huddersfield; Mr. W. Pinckney, Salisbury; Preston Royal Infirmary, Secretary of.

R.—Messrs. J. Robbins and Co., Lond.; R. W. M.; Dr. W. P. Richardson, Newcastle-on-Tyne; Royal Lancaster Infirmary, Secretary of.

S.—Dr. H. A. Smith, Ealing; Dr. S.; Smedley's Hydropathic Co., Matlock, Manager of; Messrs. W. H. Smith and Son, Manchester; Messrs. Squire and Sons, Lond.; S. R.; S. G. M.; S. V. H.; Mr. J. Smith, Liverpool; Messrs. A. F. Sharp and Co., Glasgow; S. G. W.; Dr. J. A. Shaw-Mackenzie, Lond.; Scarborough Hospital, Secretary of; Mr. L. Stone, Newcastle, Ireland; Mr. J. Stein, Dublin.

T.—Dr. W. J. Tilley, Warwick; T. K. W., Queensland; T. K. C.; Mr. C. Terry, Bath; The Thorne, Hayes; Mr. J. L. Thomas, Cardiff; Tasmanian Eucalyptus Oil Co., Lond.; Dr. A. Thorn, Skipton.

V.—Victoria Hospital for Sick Children, Lond.; V. F. A.

W.—Mr. P. Williams, Dunster; Dr. R. B. Wild, Manchester; W. R.; W. A. W.; W. S.; West Bromwich District Hospital, Secretary of; W. C. D.; Dr. J. T. Wilson, Hamilton; Dr. Forbes Winslow.

An original and *novel* feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Milroy Lectures

ON

THE EARTH IN RELATION TO THE PRESERVATION AND DESTRUCTION OF CONTAGIA.

Delivered at the Royal College of Physicians of London

BY G. V. POORE, M.D., F.R.C.P. LOND.,

PROFESSOR OF MEDICAL JURISPRUDENCE AND CLINICAL MEDICINE UNIVERSITY COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.[1]

Delivered on Feb. 28th, 1899.

ENTERIC FEVER.

MR. PRESIDENT AND GENTLEMEN,—Enteric fever has of late years much occupied the attention of epidemiologists and bacteriologists and our knowledge of its definite relationship to filth, milk, and water has undergone considerable increase. The laboratory experiments connected with enteric fever are of great interest and value, but it would be, to say the least, hazardous to build upon them any measures intended for practical sanitation. It must never be forgotten that the typhoid bacillus does not fulfil one of Koch's postulates. The disease produced by the inoculation of guinea-pigs with pure cultivation of typhoid bacillus has but a remote resemblance to the disease which we clinically know as enteric fever, a disease which seems limited to the human species. Sidney Martin[2] found that "none of the ordinary cultures of the typhoid bacillus obtainable in the laboratories will kill an animal"[3] but that it may be rendered virulent by inoculation and transference through a succession of peritoneal cavities and also by injecting simultaneously the products of other micro-organisms, such as streptococcus or bacillus coli communis. It is noteworthy that the bacillus coli communis and Gaertner's bacillus when subjected to similar manipulations are as toxic to rabbits as is the typhoid bacillus. It must be remembered that "pure cultivations of the bacillus typhosus cannot be said to exist in nature." We recognise, and it may be taken as proven, that the main cause of the endemicity and epidemicity of enteric fever in this country is to be found in the fæces of the patient, and yet Martin tells us that while the bacillus is invariably found in the spleen and mesenteric glands and in intestinal lesions "it is found in some cases in the motions of typhoid fever and also in the urine."

Dr. J. R. Carver, working under Delépine at Manchester, found the typhoid bacillus twice in 20 samples of typhoid fæces and once in 16 samples of typhoid urine.[4] Martin, working with sterilised soils, has shown that in soils which are more or less "polluted" with organic matter the bacillus typhosus will continue to live and spread at ordinary temperatures, but that in virgin soils (both sandy and peaty) the pure cultivations of the bacillus die out from some unexplained cause. Martin gives one experiment[5] to show that in unsterilised soil containing much organic matter the bacillus may continue to live, but as yet there has been no evidence of spreading. John Robertson and Maitland Gibson[6] collected 30 samples of soil from areas which they considered likely to be infected. "In not one single instance was the bacillus typhosus found."

These gentlemen carried out experiments in a field (soil, eight inches of clayey loam on 10 inches of sand and clay on stiff yellow boulder clay); each experimental patch had the turf removed and nothing was allowed to grow upon it. The patches were 18 inches square. Three patches were inoculated with 200 cubic centimetres of a pure cultivation of the bacillus typhosus mixed with one and a half gallons of tap water, No. 1 on the surface, No. 2 nine inches deep, and No. 3 18 inches deep, the top soil being removed and replaced. This was done on May 30th, 1896, and on August 26th the bacillus typhosus was found three inches below the surface of each and at nine inches below the surface of No. 2 and No. 3 and also at 18 inches below the surface of No. 3. On Oct. 20th there were practically the same results. On Nov. 27th the bacillus typhosus could not be found in either patch. Towards the end of August, 1896, three other patches (Nos. 4, 5, and 6) were inoculated in the same way and on Nov. 27th no bacillus typhosus could be found. These patches were three feet square. On Jan. 17th, 1897, patches Nos. 4, 5, and 6 received two gallons of very weak beef tea which was repeated at fortnightly intervals till June 3rd, 1897, when on examination the organism was easily found. No organism was found at this date in patches Nos. 1, 2, and 3, which had not been fed with bouillon. Practically the same result was obtained on July 11th. The persistence of the bacillus typhosus appears to depend on feeding it with fluid nourishment. A sewer leaking into the soil would do this or liquid filth in a privy. It was shown that the organism would grow three inches downwards or upwards from a depth of 18 inches. The slight downward growth might be due to mechanical conditions. The effect of sunlight does not penetrate far.

Laboratory experiments went to show that vegetation (grass) prevented the growth of the organism. This may go to explain "why typhoid fever is so much more prevalent in towns than in rural districts." Attempts to prove the aerial conveyance of the organism from liquid filth failed.

Further allusions by Dr. J. Robertson to these experiments were made later in the year,[7] in the course of which he said: "During the winter months organisms disappeared from the surface soil and from these experiments I was led to believe that the deeper layers acted as a sort of shelter during the winter months from which the organism sallied forth to the surface during the warmer months." He had not noticed any relation between typhoid fever and the rise and fall of the ground water, but he thought it was most common in places where the ground water is near the surface. The bacillus typhosus quickly dies out in grass-covered areas.

Let us now turn from these experiments which, after all, are very artificial to the practical experiences of sanitarians in the matter. It may be premised that Martin's experiments show that the bacillus typhosus will grow in any soil rich in organic matter, and that although aerobic it can be cultivated as an anaerobe even in an atmosphere of carbonic acid,[8] and the bacillus seems to be definitely destroyed by sandy or peaty "virgin" soils. Robertson and Gibson cultivated the bacillus on a soil in which clay predominated. Sir Charles Cameron is of opinion that it flourishes in gravel. At Dublin on August 23rd, 1898, he said, speaking of enteric fever: "That there is a connexion between enteric fever and the soil is shown by the results of observations of the distribution of more than 4000 cases of the disease in Dublin. Where gravel forms the site of streets there is far more typhoid fever than in districts which rest upon the stiff boulder clay. This is clearly owing to the fact that the bacillus typhosus, which is aerobian—that is, requires oxygen—can get it more freely in the loose gravels than in the stiff clays. In the gravel, too, there is a much greater space for the development and movement of the bacilli."

Dr. Scurfield of Sunderland said that "the greater part of the county of Durham in which typhoid fever had been prevalent during the last few years was covered with stiff boulder clay, and in the urban district of Sunderland typhoid fever had been just as prevalent in the boulder clay as in the houses built on sand or gravel." Pettenkofer, the chemist of Munich, is the person who is mainly answerable for the theory that enteric fever is due to a soil organism which grows with maximum vigour when the level of the ground water falls.

Dr. Christopher Childs in a valuable paper which appeared in THE LANCET[9] has placed us in possession of important facts. Munich lies on a bed of gravel 1700 feet above sea level. Between 1851 and 1896 the population has increased from 124,000 to 412,000, so that modern Munich is largely a new city. Up to 1865 Munich was a city of soakaway cesspools and filthy surface wells, and it was not till 1858 that the cesspool system began to be remedied and not till 1865 that the water-supply began to be improved. Pettenkofer's early investigations, Dr. Childs says, led him to the conviction "that in Munich there was not the slightest connexion between the drinking water and the typhoid,"[10] and this in spite of the fact that the water was shown *on analysis* to be organically polluted. The analyses and general investigations of the earlier date have been very imperfectly *recorded, but there* is evidence, says Dr. Childs, that the water was much *worse* in the earlier periods than latterly. Of Pettenkofer's personal investigations Dr. Childs says: "I have not succeeded in finding *recorded details* but they derive their weight from the high authority of Pettenkofer himself." The enteric death-rate which per short sharp shower might do infinite mischief at Tutsham-in-Field and yet be insufficient to affect the level of the subsoil water in Maidstone. Let us look at the facts of the epidemic from this point of view.

---

[3] When therefore Sir Richard Thorne in commenting upon Martin's pure cultivations of bacillus typhosus in sterilised soil says that they yielded the bacillus "presumably in virulent phase" (Local Government Board Reports, 1897–98, p. 23), his presumption is scarcely warranted by the facts.

[10] This may have been due to the fact that the wells were all equally bad.

The incubative period of enteric fever is stated by the Clinical Society of London to vary between five and 23 days. I am justified, therefore, in assuming that the majority of those who might receive a dose of poison to-day would be attacked between the seventh and twenty-first day following. Between June 28th and August 7th there had fallen only 0·21 inches of rain. At the end of a dry period the delay in the distribution of water would not be great, but it is obvious that a house cistern might be charged with infective material and considerable delay might occur before the attacks, if the bulk of the household were away. After 40 days of drought rain fell to the extent of 0·44 inch on August 7th and 8th, and 0·13 inch fell on August 15th. On August 17th and 18th there was a fall of 0·53 inch, and if this rain washed infective material to the reservoir it should cause attacks between August 24th and Sept. 9th. *The first attack of the epidemic* is stated to have occurred on August 23th and between that and Sept. 8th there were 101 attacks. On August 26th hop-picking commenced and the population round the Tutsham spring was necessarily increased. On that day there fell 0·35 inch of rain, the *heaviest fall in any one day since May 20th.* The effect of this shower should become manifest between Sept. 2nd and Sept. 16th. The attacks down to August 8th have been previously given, but between the 8th and 16th there were 335 attacks. On Sept. 1st there was 0·31 inch of rain, again on Sept. 5th in the very middle of the hop-picking there fell 0·44 inch the heaviest fall since March 2nd. The effect of this should become manifest between Sept. 12th and 26th. *Omitting the cases down to* and including the 16th we find that between the 17th and 26th inclusive there were 625 attacks. There was 0·27 inch on Sep. 8th, hop-picking being still in progress. This would carry us on to Sept. 27th, 28th, and 29th, in which days there were 122 cases. On Sept. 18th and 19th *(hop-picking having come to an end on the 13th)* there fell 0·51 inch. This would take us down to Oct. 9th and we find that from Sept. 30th to Oct. 9th there were 237 attacks. On Sept. 20th the Tutsham springs were cut off, the effect of which would not be fully manifest for three weeks. On Oct. 12th the daily attacks suddenly dropped from 18 to seven.

It must be borne in mind that the Tutsham spring had presumably sent a considerable dose of muddy water to the Barming reservoir on Sept. 18th and 19th, the very day before it was cut off, when there fell 0·51 inch of rain, and the influence of this would be felt up to Oct. 11th at least. *On Oct. 11th and 12th the daily attacks fell from 18* to seven and never rose again above nine. We must remember that after the Tutsham springs had been cut off there was the possibility of poison lurking in the foul Barming reservoir, the water pipes, and the house cisterns. On Sept. 29th there fell 0·83 inch of rain, a shower of tropical severity, and it is exceedingly likely that in the stirring up of the town sewers there may have been some leakage into the water service. There is no evidence on the point, but such things do happen at such times. In any case the effect of the wholesale poisoning of part of the water system which had taken place would be likely to endure for some time. It was not till Oct. 18th that the implicated water system was in great part (but not wholly) disinfected and this process was not completed entirely until Nov. 4th. The full benefit of this would show itself three weeks later (Nov. 25th). In the weekly returns of attacks (see Table I.) there were only four for the week ending Dec. 4th, as against 13 for the week ending Nov. 27th. Subsequent to Nov. 27th there were only 17 attacks.

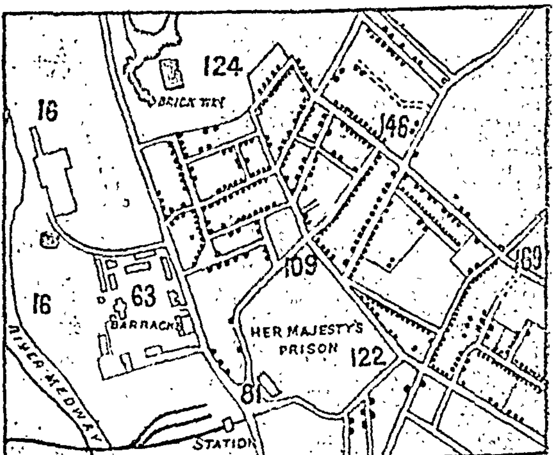
The epidemiological facts of this outbreak are quite compatible with the theory that the dirty water supplied from Tutsham-in-Field was the main cause of the outbreak, and I do not think that the effects of the contamination could be expected to finally disappear until three weeks after the completion of the disinfection of the water service on Nov. 4th. The inspectors in their report fix Oct. 18th as the day when the influence of the Farleigh water ceased to be felt in Maidstone and they say (p. 32): "Nearly all the cases notified after Oct. 18th (some 280 in number) are to be regarded as having had a cause other than the consumption of Farleigh water." This opinion seems to imply that in the estimation of the inspectors the disinfection of the Farleigh water system which began on Oct. 16th and continued until Nov. 4th was superfluous and useless.

Speaking of the 280 cases they continue: "By Mr. M. A. Adams they were referred to direct infection from previous cases and to unsanitary conditions of water-closets, drains, and sewers. This explanation appears to us to be the probable one if the unsanitary conditions referred to be taken in the wide sense of including the fouling of the soil by leakage from these defective drains and sewers. Recent researches into the life-history of the bacillus of typhoid fever go to show that this organism finds in a soil contaminated with foul matters from leaky sewers, drains, and cesspools conditions especially favourable to its vitality and multiplication. *That the soil on which Maidstone stands is thus contaminated was set beyond doubt by the evidence put before us.* To the existence of these conditions is mainly, we consider, to be attributed the remarkable persistence of fever in Maidstone after the primary cause of the outbreak had been removed by cutting off the Farleigh water-supply."

Do the facts of the case really establish the conclusion which the inspectors say is "set beyond doubt"? I do not find a single word in the report or a single experiment to prove that the bacillus typhosus was growing in the soil of Maidstone. The epidemic is remarkable not only for its severity but from the fact that six gentlemen, all eminent for their skill in bacteriology, failed to discover a single typhoid bacillus. The bacteriological investigations were upon a scale which was quite unprecedented and in so far as the bacillus typhosus was concerned were entirely and absolutely negative. It may be, as the inspectors hint was the case, that the bacillus typhosus was permeating the soil of Maidstone in November, December, and January very much as a blue mould permeates a cheese, but no examination of the soil is recorded in the report. There are facts, however, which make strongly against any such contention. These were the total escape of the barracks and prison.

On page 26 of the report is the following paragraph: "The barracks and the Maidstone prison are both within the borough and both are connected with the town sewers. The population of the barracks was 300, this total including 166 men, 44 women, and 88 children. The water supplied to the barracks is that of the Boarley system of the water company's supply. *No case of typhoid fever occurred in the barracks* during the year. At the prison the average population throughout the year was 171, the total number of prisoners received being 1925. The water used on week-days is from a well 34 feet deep sunk in the Hythe beds of the lower greensand. *On Sundays water is turned on to the prison* from the Boarley mains. There have been no cases of typhoid fever or diarrhœa among the prisoners or staff during the whole of 1897." During the five months (August to December) there were probably 800 persons who drank water from the 34-feet well sunk in the "contaminated" soil of Maidstone. A reference to the map (Fig. 5) will show that the area of the prison is closely hemmed in on the north and east by fever-stricken houses and the escape of the prison and barrack populations is most remarkable. Neither rise nor fall of subsoil water brought typhoid fever or diarrhœa to the prison.

FIG. 5.



"Spot" plan of surroundings of Maidstone barracks and prison. The big numerals show the height above sea-level. The black dots are fever-stricken houses.

The investigations connected with the Maidstone epidemic are of great interest as pointing to the wonderful protection which the humus affords to the underlying water against pollution from above. The whole of the Farleigh springs were of the same character, the catch-pits of many of them were liable to invasion in time of flood, and the gathering ground of most of them was highly cultivated and manured land. And yet none of them (always excepting Tutsham-in-Field) afforded evidence of serious bacterial impurities. It may be added that in the third quarter of 1898 there was one death from enteric fever in Maidstone and another death from the same cause in the fourth quarter, so that the "contaminated" soil of Maidstone was not able to contaminate the inhabitants during the drought of July, August, and September or the rains of October, November, and December *of last year.*

IMMUNITY.

Bacteriologists have abundantly proved that the germs of disease are ubiquitous. They are found in earth, air, water;

in the dust and on the walls of our dwellings, in clothing, in meat, milk, bread, and even occasionally, as Andrewes has shown, in hot baked rice-pudding. With regard to most of the necessities of life we hear the cry of "unclean," "unclean," until the wonder is that we are any of us left alive to warn our neighbours. The fact that many of us manage to live to a respectable age and to die from something which is non-infective cannot but make us consider whether after all the immunity of the individual is not the fact which tends more than any other to the improvement of the public health. It is wholesome for us to remember that the greatest sanitary achievement of our time has been the practical disappearance of typhus fever. Of the *causa causans* of this disease we know nothing. Its absolute disappearance has not been produced by successful germ hunting. Its disappearance is probably due to the improved conditions under which the masses of the population live as regards food and cleanliness. Few of us doubt that if this country should become involved in war and food should become dear and scarce in consequence the relative immunity of the population would be lessened and typhus fever would re-assert its sway. Whether we succumb to an infective disease or not probably depends in great measure to the dose of the poison which we receive. When an endemic disease such as enteric fever becomes epidemic it is due to the sudden dissemination of a poison in relatively large or virulent doses. Even in the most severe epidemics it is rare for more than 10 per cent. of those who have run obvious risks of receiving the poison to be attacked. The questions of virulence and vulnerability are most important. It seems to be well-established that the virulence of some of the pathogenic microbes varies immensely with the conditions of soil, temperature, air, sunlight, &c., under which they are grown, and it is a fact that must be remembered that it is not always the pure cultivation which manifests most virulence. Many infective diseases assume a virulence in the tropics which is rarely met with in temperate countries. This appears to be true of tropical malaria, enteric fever, cholera, yellow fever, anthrax, and tetanus. In hot countries where a temperature equal to the optimum for the growth of many pathogenic microbes is often continuously maintained for weeks in succession, the risks of contagion and the danger of uncleanliness must often have become apparent in a manner more convincing than is the case among us. The repeated injunctions as to uncleanliness in the Mosaic law and the rigid rules laid down as to the conditions which made a man unclean and which necessitated his subsequent purification must have been the outcome of experience. To eat with unwashed hands in a tropical country and without knives and forks would clearly be to run considerable risks. The regulations in force among the Hindus were even more stringent, and although some of the regulations may appear to us to be extravagant and nonsensical it is impossible not to admit that most of them have for their aim the protection of the individual and his fellow man from the risks of infection.[15]

There can be no doubt that the health and vigour of the individual is all-important in relation to infective disease. The enervating influence of a tropical climate upon Europeans is recognised as a potent predisposing cause of infective disease and if to the effects of climate be added those of inordinate fatigue and insufficient food the risks of infection getting a hold of the organism are greatly increased. Director-General Jameson told us last year in the debate on enteric fever already alluded to that "in almost all the posts occupied by European troops coöperating with the various columns in Afghanistan, extending from the British territory up to Kabul and Kandahar, cases of enteric fever appeared, *some of which posts were occupied probably for the first time* since the world began." In the Nile expedition in 1889 those troops suffered most which had undergone most exposure and fatigue "and it becomes difficult to resist evidence tending to show that in the causation of this disease there may be more factors than are generally acknowledged." Dr. Maclean, R.N. (*in a letter to Sir J. Fayrer*), alludes to the occurrence of enteric fever in the Island of Ascension, under circumstances of close observation where no connexion could be traced with defective sanitary arrangements, though it is probable that malarial influences did occur. "There is no such thing as a drain or a cesspool in the island, all the sewage and other filth being removed daily and thrown into the sea to leeward of all dwelling-houses. The water, partly collected from the roofs of buildings during rain and partly condensed, is stored in iron and cemented stone tanks and removed from all possible sources of contamination." It is of course possible that in a case such as this the bacillus typhosus may be lying dormant in the body ready to assert itself when bodily enfeeblement reaches a certain pitch. It has been asserted (and the assertion received the support of the late Professor Kanthack) that the bacillus typhosus may be found in an abscess years after the attack and the same thing holds good in a less degree with regard to the microbes of diphtheria and cholera.

Nothing is better established with regard to tubercle than its relation to overcrowding and unwholesome occupations. Three times as much tuberculous disease occurs in the centre of London as at the outskirts and an hotel servant in London runs a risk of dying from tubercle nearly 10 times as great as that of the farm labourer. In our combat with this disease we must by no means confine our efforts to microbe hunting. So again with "filth diseases," we must remember that almost all infective diseases are especially fatal to those who live in the midst of filthy surroundings. It is not, I think, at all necessary to assume, although it is possibly the case, that specific organisms are growing in the filth. In the cramped dwelling of the artisan where the privy is often barely six feet from the back door the risks of fæcal befoulment of the food or person are very great and when in such places large pails of fæces are left to putrefy for a week or more it is not to be wondered at that the inhabitants should show an undue predisposition to the infection of enteric fever, as has been pointed out by Boobbyer and others.

---

[15] In the Abbé Dubois's book on Hindu Manners, Customs, and Ceremonies, translated by Beauchamp (Clarendon Press, 1897), will be found a chapter (vol 1, p 238), largely culled from the great book of Brahmin ritual called "Nittia-Karma," on hygienic rules and among them a section on "Rules to be observed by Brahmins when answering the Calls of Nature." 1. Taking in his hand a big *chembu* (brass vessel) he will proceed to the place set apart for this purpose which should be at least a bowshot from his domicile. 2. Arrived at the place he will begin by taking off his slippers which he deposits some distance away and will then choose a clean spot on level ground. 3. The places to be avoided for such a purpose are, the enclosure of a temple; the edge of a river, pond, or well; a public thoroughfare or a place frequented by the public; a light-coloured soil; a ploughed field; and any spot close to a banyan or any other sacred tree. 4. A Brahmin must not at the time wear a new or newly-washed cloth. 5. He will take care to hang his triple cord over his left ear and to cover his head with his loin cloth. 6. He will stoop down as low as possible. It would be a great offence to relieve oneself standing upright or only half stooping, it would be a still greater offence to do so sitting upon the branch of a tree or upon a wall. 7 While in this posture he should take care to avoid the great offence of looking at the sun or the moon, the stars, fire, a Brahmin, a temple, an image, or one of the sacred trees 8. He will keep perfect silence 9 He must chew nothing, having nothing in his mouth, and hold nothing on his head. 10. He must do what he has to do as quickly as possible, and rise immediately. 11. After rising he will commit a great offence if he looks behind his heels. 12 If he neglects none of these precautions his act will be a virtuous one, and not without merit; but if he neglects any of them the offence will not go without punishment. 13. He will wash his feet and hands on the very spot with the water contained in the *chembu* which he brought. Then taking the vessel in his right hand and holding his private parts in his left, he will go to the stream to purify himself from the great defilement which he has contracted. 14. Arrived at the edge of the river or pond where he purposes to wash himself he will first choose a suitable spot and will then provide himself with some earth to be used along with the water in cleansing himself. 15. He must be careful to provide himself with the proper kind of earth and must remember that there are several kinds which cannot be used without committing an offence under these circumstances Such are the earth of white ant nests, potter's earth, road dust, bleaching earth, earth taken from under trees, from temple enclosures, from cemeteries, from cattle pastures, earth that is almost white like ashes, earth thrown up from rat-holes and such like. 16. Provided with the proper kind of earth he will approach the water but will not go into it. He will take some in his *chembu*. He will then go a little distance away and wash his feet and hands again. If he has not a brass vessel he will dig a little hole in the ground with his hands near the river side and will fill it with water which he will use in the same way, taking great care that this water shall not leak back into the river. 17. Taking a handful of earth in his left hand he will pour water upon it and rub it well on the dirty part of his body. He will repeat the operation, using only half the amount of earth, and so on three times more, the amount of earth being lessened each time. 18 After cleansing himself he will wash each of his hands five times with earth and water, beginning with the left hand. 19. He will wash his private parts once with water and potter's earth mixed. 20 The same performance for his two feet, repeated five times for each foot, beginning, under the penalty of eternal damnation, with the right foot. 21. Having thus scoured the different parts of his body with earth and water he will wash them a second time in water only. 22. After that he will wash his face and rinse his mouth out eight times When he is doing this last act he must take very great care to spit out the water on his left side, for if by carelessness or otherwise he unfortunately spits it out on the other side he will assuredly go to hell. 23. He will think three times of Vishnu and will swallow a little water three times in doing so.

But it must be remembered that wherever putrefaction is going on and wherever anaerobic organisms are growing in a filth-sodden soil unwholesome gases, such as CO_2, H_2S, CH_4, and H, are being given off and it is impossible not to admit that the breathing of these gases, from week end to week end in the crowded courts of a great city may so lower the vitality of the body as to increase its vulnerability to infection of all kinds. But these gases *which are naturally given off from sewers and sewer traps*, from cesspools, from privies and from water-logged and filth-sodden soil are accompanied by "odours" which are often too subtle for the chemist to analyse but which, nevertheless, are sufficiently potent to make a strong man sick and faint and to reassert themselves in the excreta 24 hours after being inhaled. The odour given off by a tropical arum at Kew some few years since during the time it was in flower and just ripe for fertilisation was of a kind which could only be described as appalling and which made it impossible to enter the house where it was growing without putting a clip on the nose and holding the breath. I merely want to emphasise the fact that odours may have a power which neither the chemist nor the bacteriologist can gauge and that we must be ready to admit that to live in stinks and filth must depress the health and increase the susceptibility to infection by microbes some of which have perhaps a greater measure of ubiquity than we are definitely aware of.

Professor Stewart Stockman[16] reports an investigation which he carried out on a septic organism which proved fatal to 380 fowls out of 400 on a poultry farm. He says: "The most important thing about this bacillus seems to me to be its fatal effect on tuberculous birds while it appears to be non-pathogenic, or nearly so, for healthy birds. It is also interesting to note that it killed a rabbit affected with the coccidium oviforme although the healthy ones were little affected by it. This observation, I think, affords fresh evidence in favour of what is taught about certain other microbes—namely, that they are only pathogenic to the enfeebled organism."

Danger of Wounds.

It is an established fact and is now universally accepted that infective organisms may gain access to the body through the smallest conceivable wound whether of the skin or the mucous membrane. The various forms of septicæmia as well as erysipelas and malignant œdema are due to this cause. Tetanus, as we have seen, is always due to the inoculation of a wound and it is a question whether anthrax of cattle is not more often caused by inoculation of a skin abrasion than hitherto has been suspected. Whether any of our common infective fevers are communicable by accidental inoculation is a moot point and one which is certain to receive a full share of attention in the immediate future. It is certain that in the transmission of plague a broken skin bears a most important part, and it may be that other infections may be conveyed in the same way. A distinguished pathologist is credited with having infected himself with enteric fever by a post-mortem wound. The infections brought about by flies, ticks, and mosquitoes are at present attracting much attention from pathologists and it seems probable that the danger of certain "soils" and climates may be shown to be due in an increasing degree to the insects which find in the localities the various conditions necessary for their existence. It may be that in some instances an abrasion of the skin made by an insect may merely serve as a point of entrance for infective organisms abounding in the surface of the soil or in the immediate surroundings of the individual and having no necessary connexion with the insect itself. It seems certain, however, that in the majority of instances which have been worked out a particular species of insect serves as an intermediary host for a specific organism which affects a specific animal. We hear a good deal in a loose and speculative way about flies conveying fever. This may be true, but we must always bear in mind what I feel inclined to call the excessive specialism of nature. Insects which feed on dung and carrion are seldom attracted by the food of human beings and I confess to being somewhat sceptical as to the accidental conveyance of infection by "flies" which heedlessly buzz first into the fæces and then into the milk. The pathologist of the future will clearly have to call in the help of the entomologist.

Practical Considerations.

The Maidstone epidemic has been very useful in directing attention to some of the common conditions which endanger water-supplies. Pasteur and all subsequent bacteriologists have directed attention to the value of the earth as a filter and it is a matter of common knowledge that a very shallow layer of compact earth will remove the bacteria and much of the organic matter from water percolating through it.

The greatest danger to shallow wells is to be found in subterranean collections of filthy fluids which leak through fissures in the earth and with a gradually increasing hydraulic pressure. If there be no such dangers in the immediate neighbourhood, then a properly constructed shallow well is safe. The lined well five feet deep which I have in the middle of my garden has given water of exceptional purity for years, notwithstanding that the ground is cultivated with human excreta to within six or seven feet of the well. Dr. Macmartin Cameron, medical officer of health for Kirkcudbright and Wigtown,[17] shares my opinion that a "surface well" properly constructed and in a selected situation is a safe source for water. Dr. Cameron's paper embodies much experience obtained in his official capacity and many of his observations are worthy of quotation as showing some of the limits of danger and safety in relation to shallow wells.

> "*The construction of new village wells.*—When the wells of a village are shown to be contaminated and a new water-supply becomes imperative it is not, as a rule, necessary—not, at least, in the province of Galloway, for which I have the honour to be medical officer of health—to press on a gravitation scheme as the only way of meeting the difficulty. A simple and inexpensive well scheme will often suffice. All that is requisite is to sink new wells outside the precincts of the village on higher ground if practicable. Commonly enough the self-same water that feeds the old wells may be tapped at a point *before it* has entered the polluted ground of the village. All that is then required to secure perpetual immunity from pollution is to obtain possession of a sufficiency of ground around each well to be devoted for all time to purposes of filtration. With a sufficient reserve (*anything, say,* from half to one acre, according to circumstances) *little or no danger* will accrue from ordinary agricultural operations beyond, but it would be better that as much as possible of the outlying ground should be left under grass. There is no safer or better water than that which a surface well in an old grass park can be got to yield. *This is an ideal* site. I should have no fear even of a top dressing of manure, provided the ground in the immediate vicinity of the well were not *profaned*.
>
> "Professor Hunter Stewart (Edinburgh) remarked that Dr. Vivian Poore's experiment with a six-feet well carefully cemented at the sides gave water which contained seven micro-organisms to the cubic centimetre and the bacillus *coli* was conspicuous by its absence. A part of the supply of the city (Edinburgh) was from wells near the Pentland Hills not more than eight feet deep, situated in highly manured land and exposed to pollution from neighbouring middens. From the water of these particular wells *of a maximum of eight feet in* depth he found a maximum of micro-organisms of 11 to the cubic centimetre and a minimum in three out of eight wells of absolute sterility. These observations abundantly supported the observations of Dr. Poore."

Reverting to the conditions which obtained at Maidstone I will mention a few considerations which, though obvious enough, are often neglected. During a drought such as occurred in June, July, and August, not only would the stiff hop land be liable to crack, but the earth-worms would retire to the lowest point in search of moisture. At such times they go deeper and deeper into the soil and lie coiled up in oval knots at the bottom of their burrows. I have upon the table a piece of a worm-burrow removed from my garden in September last at a depth of more than two feet. It is more than a quarter of an inch in diameter and would act as a drain from the surface to the deeper parts. This question of worm-burrows is one of great practical importance to sanitarians because, especially after a drought, they may serve to conduct surface water to considerable depths without its really being influenced by that biological filter the humus. Darwin[18] says that although worms generally live near the surface they may burrow to a considerable depth during long-continued dry weather and severe cold; the depth varies with the soil.

> "In a bed of fine sand overlying the chalk which had never been disturbed a worm was cut into two at 55 inches and another was found here at Down in December at the bottom of its burrow at 61 inches beneath the surface. Lastly, in earth which had not been disturbed for many centuries a worm was met with at a depth of 66 inches and this was in the middle of August. The burrows are lined with viscid earth voided by the worm which gives at once smoothness and a certain amount of durability to the burrow."

Then, again, we must not forget the effect of harvest on the soil. Before harvest the amount of moisture retained upon the growing plant and absorbed by the still active root would prevent anything except the heaviest rain from penetrating, although even at such a time one must admit that even half a pint of water if thrown on a suitable place might travel *viâ* clay-crack and worm-burrow to a depth of five feet or more. When harvest begins not only is the earth deprived of its green protecting mantle but the upward drainage of the root action ceases and with the falling temperature of autumn and the lessened evaporation the rain which falls has an ever-increasing power of penetrating the soil. In a hop garden the first step in harvesting is the removal of the pole, and the hole thus left is capable of conducting rain water to a depth in the soil of two feet or more. *If, therefore, there be open-jointed stoneware pipes in a hop garden at a depth of two or three feet from the surface it is possible (nay, likely) that when the hop-poles are removed a surface channel three or four inches in diameter may communicate with these pipes and a heavy rain may wash solid matters into them from the surface.*

[17] Brit. Med. Jour., August 13th, 1898.

[18] Vegetable Mould and Earth-worms, p. 111, *et seq.*

There are other practical matters which need consideration in relation to liability of springs to suffer from surface contaminations. If a plant or tree dies—be it hop, beech, hazel or what not—the roots, instead of helping the upward drainage of the soil and preventing surface water from reaching the springs may serve as a direct guiding channel from the surface to the spring. And if the spring be artificially maintained by under-draining it with open-jointed pipes (an operation which involves a considerable disturbance of the ground and its artificial re-making) this danger is considerably increased. Burrowing animals are necessarily a danger in this connexion and if rats or rabbits establish themselves anywhere near the outcrop of a spring they must be exterminated. Rats and rabbits sometimes burrow very deeply, but I have not been able to get any authentic statement as to the maximum depth in the soil to which they may penetrate. Rats are animals which the sanitarian is bound to regard with some suspicion. In relation to the plague they seem to be a very definite danger and when they crawl from the sewers (their favourite lurking place in towns) to our houses it is possible that they may be at least as dangerous as sewer gas. Rats occasionally make their homes in dungheaps, especially if such heaps be made in outlying places and are long neglected. It is well known that they invade corn ricks in spite of elaborate precautions, but it is safe to regard the rat as a haunter of foul places and a lover of filth and its presence among us is often due to our permitting accumulations of filth and our delay in putting filth to its proper use.

Although it is probable that a very few inches of soil may, if properly tilled and cultivated, serve as an efficient protection to the subsoil water, we must nevertheless be mindful of the accidents which may serve to conduct filth from the surface to the springs. The danger of having a catch-pit flooded from the surface is one which can easily be guarded against by covering with suitable structures. The ground above the outcrop of a spring ought to be carefully turfed to a point which is six or seven feet above the level of the spring. A spring used as a water-supply must be very carefully watched. If the water become turbid or if a worm find an entrance to the catch-pit the use of such water should be discontinued or it must be boiled and filtered until the cause of the turbidity be satisfactorily demonstrated. Such springs should always be carefully inspected during heavy rains, because it is at such times especially that shallow springs establish surface relations.

The question arises whether it is safe to allow the gathering ground of a spring to be cultivated? This is a national question of the very greatest importance. No nation which is dependent upon its native soil for food production could possibly afford to raise such a question What would a Chinese say if you told him that the water of his well contained a trace of ammonia and had a permanent hardness above the local standard and therefore his tea-gardens and rice-fields must remain unmanured and be converted to permanent pastures? His answer to the "foreign devil" who ventured to propound such a theory had better go unrecorded. But in China they boil the water before drinking it and they do not seek to fix the responsibility for the absolute purity of the water of a district upon a single underpaid individual; nor do they talk about "manslaughter" when a break-down in the arrangements from some cause, natural or artificial, brings about an outbreak of disease.

Provided there be a fairly thick layer of earth above the spring I am inclined to think that there is safety rather than danger in the cultivation of the overlying soil. Any spring which is covered by seven feet of soil—that is, six inches more than the depth of the deepest recorded earth-worm, might be considered safe from the risk of unchanged organic matter soaking into it from above.[10] In the first place, the cultivation of the land ensures that it is visited more or less frequently by individuals more or less intelligent. A gathering ground for water which is remote from the haunts of man has dangers of its own. Rats or rabbits may burrow in it and these as well as other animals and birds may provokingly die in the runnels which primarily collect the rain-water and I cannot understand how anybody who has ever walked over a moor can maintain the thesis that water running off a neglected waste is safer to drink than that which has percolated through well-cultivated land.

Last year I visited a spring which was being used for public purposes and which was and had been supplying water of excellent quality. The spring which rose in a little copse lying in a natural dell in a remote and seldom visited spot was enclosed and protected against surface washings which the configuration of the ground would certainly conduct towards it in times of flood. Some of the trees were dead and their stumps and roots were permeated with fungi and were rotten and one could not but regard it as possible that these rotten roots might serve as conducting channels from the surface to the water which was running beneath to the neighbouring town. Possibly the workings of rabbits or other burrowing beasts had hastened the death of some of the trees. If so, the burrows might run very close above the gathering water. Further, there was evidence to show that this dell was visited by an occasional tramp and had been made a playground by the children from the nearest group of cottages It is clear that the non-cultivation of this particular spot was a source of danger rather than of safety to the purity of the spring.

Enteric fever is a disease especially liable to become epidemic in the autumn. The autumn is the time of year when after removal of the crops the parched earth is soaked and it is also the time of year when there are large accumulations of manurial matters waiting to be spread upon the land. In the summer the yield of springs is seldom increased no matter how heavy may be the rains. The water which falls upon the earth is all absorbed by the roots of growing plants and to a large extent mounts upwards in the plant to help metabolism and to quicken growth. With the ripening and harvesting of the crops root action ceases, water which falls upon the earth tends more and more to percolate, and when the early frosts have given their death-blow to the greenery of summer then the springs begin to rise and to yield more water. The nitrification and final solution of organic matter in the soil goes forward mainly, if not entirely, in the upper layer and it is doubtful if any appreciable amount of oxidation takes place in the parts which are beyond the reach of tillage. A certain proportion of the mineralised organic matter necessarily escapes absorption and percolates with the water and if there be much unused nitrates remaining in the soil after harvest the amount which percolates to the springs may be considerable. If nitrates be placed upon the soil in the form of artificial manures they are often dissolved and washed beyond the reach of plant roots with the first heavy shower. Not only nitrates but soluble salts of ammonia are placed on the ground in large quantities and the presence of free ammonia in the drainage water of cultivated land which has been *artificially* manured need not be an indication of pollution in the proper sense. It must be very hazardous to draw just conclusions as to the wholesomeness or otherwise of water from the amount of nitrates in it.

---

[10] For the same reason, although I agree with Dr. M Cameron, I am of opinion that the first eight feet of all "shallow" wells should have an impermeable lining

---

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—The annual meeting of this institution was held on Feb. 20th under the presidency of Major Whitting. The report stated that 269 in-patients had been admitted, 542 out-patients treated, and 727 casualties attended. The members of the Provident Dispensary at the end of 1898 numbered 2279. The financial statement showed that the general receipts for the year amounted to £1909, and after meeting expenses a balance of £5 remained.

ABSTRACT OF

The Arris and Gale Lectures

ON

THE ANATOMY AND SURGERY OF THE PERITONEAL FOSSÆ

Delivered before the Royal College of Surgeons of England on Feb. 27th and March 1st and 3rd, 1899,

BY B. G. A. MOYNIHAN, M.B., M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY.

LECTURE I.

Delivered on Feb. 27th, 1899.

THE DUODENAL FOSSÆ; DUODENAL HERNIA.

MR. PRESIDENT AND GENTLEMEN,—The subject which I have chosen for the lectures which by the grace of the Council of this College I am permitted to deliver is the Anatomy and Surgery of the Peritoneal Fossæ. In the first lecture I propose to consider the anatomy of the duodenal fossæ and the various forms of duodenal hernia. In the second I shall describe the pericæcal fossæ and discuss the reported cases of hernia occurring in the neighbourhood of the cæcum. In the third lecture the intersigmoid fossa and intersigmoid hernia and hernia into the foramen of Winslow will be discussed.

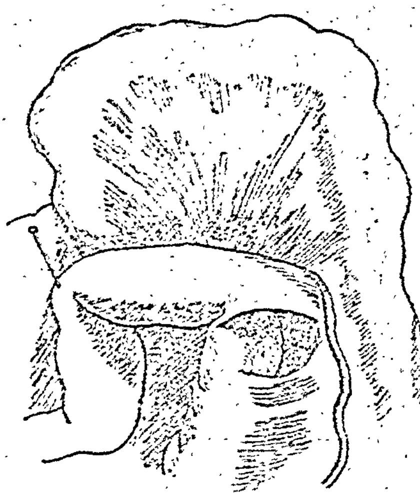
THE DUODENAL FOSSÆ.

In describing the anatomy of the various fossæ found in the duodenal region it is well to clear the ground a little by referring to the exuberant and redundant nomenclature which has been adopted by various writers at different periods. Most unfortunately the same name has been adopted to describe entirely different fossæ. The name "duodeno-jejunal" has been applied to at least three separate pouches. It is a matter of no little difficulty to choose an exactly appropriate name. I have given the most apt title first and the alternative names are mentioned in order to avoid misunderstanding. I have examined for the purposes of these lectures over 200 bodies; not consecutively, but when time and opportunity permitted. In all cases where a vestige of old peritonitis existed I have made no record. I have also examined the bodies of 34 fœtuses of all ages. The varying descriptions given by writers to the same fossa and its determining fold may be readily accounted for. The folds and fossæ vary in their appearance according to the age of the patient. In the fœtus and in children they are very distinctly and clearly seen. In the aged, owing to the deposit of fat, traction effects, and so forth, they may become considerably altered. The true typical forms are seen in the young and it is upon observation of young subjects that I have based my descriptions. I recognise the following fossæ as occurring in this neighbourhood:—(1) The superior duodenal fossa; (2) the inferior duodenal fossa; (3) the posterior duodenal fossa; (4) the duodeno-jejunal fossa; (5) the intermeso-colic fossa; (6) the infraduodenal fossa; (7) the paraduodenal fossa (the fossa of Landzert); (8) the mesenterico-parietal fossa (the fossa of Waldeyer); and (9) the para-jejunal fossa (the fossa of Brösike).

1. *The superior duodenal fossa* (recessus duodeno-mesocolicus superior) is present in from 40 per cent. to 50 per cent. of cases. (Fig. 1.) It may exist alone or with the inferior duodenal fossa. It lies to the left of the ascending portion of the duodenum. It is bounded in front by the superior duodenal fold, triangular in shape, presenting a lower free margin, slightly concave, the inner end of which is blended with the peritoneum on the duodenum and the outer margin of which is lost on the posterior parietal peritoneum.

2. *The inferior duodenal fossa* (fossa duodeno-jejunalis of Treitz; recessus duodeno-mesocolicus inferior of Brösike). (Fig. 1.)—This is the most frequent of all the peritoneal fossæ in this region, being present in from 70 to 75 per cent. of cases. It is placed on the left side of the ascending portion of the duodenum, opposite the third lumbar vertebra. The orifice looks upwards and is opposed to the mouth of the superior fossa. The fossa is bounded by the inferior duodenal fold, thin, sharp, and with a concave upper margin. The inferior mesenteric vein and the left colic artery are generally found well to the left side of the point of fusion of the fold with the parietal peritoneum. The fossa is liable to variation in size and extent. Treves has figured many of the aberrant forms. In general the first joint of the middle finger can be easily passed into the fossa. The superior and inferior duodenal folds are not infrequently blended at the outer extremities, so that a single oval orifice leads to the two fossæ. The anterior fossa very commonly extends some little distance behind the ascending portion of the duodenum.

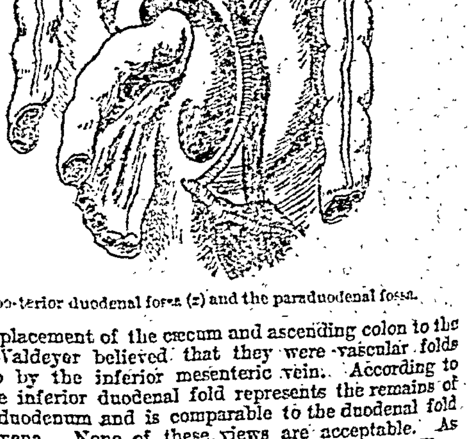
FIG. 1.



The superior and inferior duodenal fossæ.

Genesis of the superior and inferior duodenal folds.—It is to Treitz (1857) that we are indebted for the first explanation given of the formation of the folds. He considered that they were traction folds due to the dragging of the intestine in the displacement of the cæcum and ascending colon to the right. Waldeyer believed that they were vascular folds raised up by the inferior mesenteric vein. According to Treves the inferior duodenal fold represents the remains of the mesoduodenum and is comparable to the duodenal fold of the hyena. None of these views are acceptable. As shown long ago by Toldt, the folds are fusion folds. They are caused by the process of "physiological adhesion" between the original left, afterwards anterior, surface of the ascending portion of the duodenum and the right or anterior

FIG. 2.



The posterior duodenal fossa (x) and the paraduodenal fossa.

surface of the descending mesocolon, and date their origin from the time when these two peritoneal surfaces were in close apposition.

3. *The posterior duodenal fossa* (Fig. 2, *x*) (recessus duodeno-jejunalis posterior of Brösike; the fossa of Gruber).—This is a small fossa lying immediately behind the upper portion of the ascending limb of the duodenum. Its orifice is directed upwards and to the left and on its right side is the plica suspensoria, a fold raised up by the muscle of Treitz. It was described as an "accessory sac" by Gruber.

4. *The duodeno jejunal fossa* (recessus duodeno-jejunalis superior).—On dragging the transverse colon upwards and the jejunum downwards and to the right there can be seen at the root of the transverse mesocolon a fossa which results from the plunging of the duodeno-jejunal flexure into the root of the transverse mesocolon. This fossa is the duodeno-jejunal; it exists in from 15 per cent. to 20 per cent. of the bodies examined. Its lateral boundaries are two folds, the duodeno-mesocolic, which are in reality the continuations backwards of the two layers of the mesentery. The fossa is bounded above by the pancreas, to the right by the aorta, and to the left by the kidney. In the floor lies the left renal vein. The duodeno-jejunal flexure is a hernial content of the sac.

5. *The intermesocolic fossa* (recessus intermesocolicus transversus).—This is probably a modification of the last fossa; it runs horizontally in the root of the transverse mesocolon. In all cases there is a marked deviation of the duodeno-jejunal flexure to the left.

6. *The intraduodenal fossa* (fossette retro-duodénale Jonnesco).—The orifice of this fossa looks downwards; its apex reaches the duodeno jejunal angle, the muscle of Treitz, and the pancreas. It is bounded in front by the posterior aspects of the horizontal and ascending portions of the duodenum, behind by the aorta, and laterally by two folds, the duodeno-parietal.

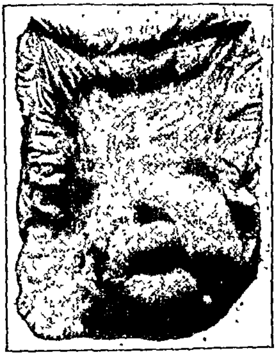
7. *The paraduodenal fossa* (Fig. 2) (recessus venosus; fossa of Landzert).—The complications of this fossa are frequent. In its typical form it may be thus described. It is placed to the left and some distance from the ascending limb of the duodenum. The fossa is caused by the raising up of a fold, the plica venosa, by the inferior mesenteric vein, a fold which may be not inaptly described as a "mesentery" for that vein. Behind, the sac is bounded by the parietal peritoneum covering the psoas, the renal vessels, the ureter, and a portion of the left kindey. Below, it is limited by the mesenterico-mesocolic fold. The orifice of the sac is wide and it looks downwards and to the right. The plica venosa consists of a vertical and a horizontal portion, the vertical being to the left and below the fossa and the horizontal bounding the fossa above. The inferior duodenal fossa may be present with the paraduodenal. In that case there is always an amalgamation of the determining folds. Such a fossa was described by Treitz and was considered by him as the normal condition.

8 and 9. *The mesenterico-parietal fossa and the fossa parajejunalis.*—These may conveniently be studied together, for they are practically the same fossa under different conditions. The fossa is situated in the first part of the meso-jejunum, immediately behind the superior mesenteric artery and immediately below the duodenum. Waldeyer who is the only observer who has noticed a fossa in this position with the intestines normal has described it as existing only in the fœtus. I have, however, seen two well-marked examples in the adult. Brösike who describes a similar or more probably the same fossa asserts that it can only be found when the first portion of the jejunum is adherent to the posterior abdominal wall. As the fossa in any case lies immediately behind the first portion of the superior mesenteric artery the jejunal adhesion is probably merely an episode and in no causal relationship with the fossa. The peritoneum of the left leaf of the mesentery lines the pouch the opening of which is to the left and the fundus to the right. A forcible enlargement of the fossa results in the lifting up of the posterior parietal peritoneum in the right half of the abdomen.

DUODENAL HERNIA.

Duodenal hernia is of two kinds. In the first the hernial sac is situated on the left side of the abdomen and in the second to the right. In both cases there may be also an upward and a downward increase, but the essential difference between the two forms lies in the varying direction of their lateral deviation. In the later stages of each the sac may practically fill the abdominal cavity. I propose to apply the terms "left duodenal hernia" and "right duodenal hernia" to the two varieties, to emphasise the fact that there is an intrinsic difference not only in the mode of growth, but also and chiefly in the points of origin of the two forms.

FIG. 3.



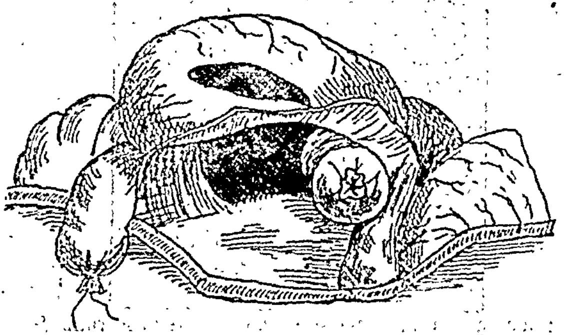
Left duodenal hernia. Mr Shattock's specimen in St. Thomas's Hospital Museum

Left duodenal hernia (Fig. 3).—This is the commoner variety; 57 cases are recorded. A perfectly typical case, for which I am indebted to Dr. T. Wardrop Griffith, is here depicted. Without discussing the matter closely it may be affirmed that only one of the fossæ above described is capable of developing into the sac of a hernia. That one is the paraduodenal fossa, or the fossa of Landzert. In all the cases recorded it has been found that in the anterior margin of the orifice of the sac lies the inferior mesenteric vein. With it for a shorter or longer distance there runs the ascending branch of the left colic artery. The anterior margin of the sac is formed, in fact, by the plica venosa. The plica venosa normally bounds the fossa of Landzert and it is in that fossa and in that fossa alone that a hernia can develop. A left duodenal hernia is characterised by three points: (1) the presence of the inferior mesenteric vein of the neck of the sac; (2) the hernia spreads either outwards towards the descending mesocolon or upwards towards the transverse mesocolon or both; and (3) the hernial sac consists of a single layer of peritoneum. Behind, the sac lies in contact with the posterior abdominal wall and in front of it there is the posterior parietal peritoneum. The orifice of the sac is situated at the back of the hernia in close approximation to the lumbar vertebræ. In a large hernia it is necessary in order to expose the neck of the sac to drag the whole tumour well over to the left side. The orifice is then seen close down to the third lumbar vertebræ. The average size of the opening is six centimetres long and four centimetres broad. The size of the hernia varies enormously. The smallest is recorded by Brösike. It occurred in a child 14 days old, and the length of intestine in the sac was between two and three centimetres. In several cases, including the first recorded by Neuebauer, the whole of the jejunum and ileum lay in the sac. As the hernia increases in size it reaches the descending colon on the outer side. In some cases the colon is pushed backwards and covered by the hernia; in other cases the hernia passes behind the colon which then lies in the anterior wall of the sac the hernial tumour appearing therefore on the outer side of the colon. The difference in the behaviour of the colon I believe to be due to the condition of its peritoneal surroundings. When no descending meso-colon is present the colon is pushed backwards by the hernial swelling; wher a descending meso-colon is present it is used up, so to spe as a covering for the sac, and the hernia passing behind A colon comes to lie on its outer side. acute

Right duodenal hernia.—This is the rare variet 13 cases, exclusive of the spec'men shown, are

This specimen, for which I am indebted to Dr. T. Wardrop Griffith, has been preserved for some years in the post-mortem room of the Leeds Infirmary. The notes of the case have not been traced, but Dr. Griffith's recollection is that the death of the patient was unconnected with the hernia. The point of origin of this hernia has never been satisfactorily explained. Jonnesco gives an unintelligible description of the process by which a left duodenal hernia is supposed to turn over to the right. Brösike believes that in all specimens which are recorded there has been a jejunal adhesion to the posterior abdominal wall. The fossa of Waldeyer (mesenterico-parietal) has entirely escaped observation by other writers. I believe it to be in this fossa that a right duodenal hernia develops. On examining the orifices of the case recorded by Dr. Barrs and the specimen placed at my disposal by Dr. Griffith this opinion seems beyond disproof. The drawing of Dr. Barrs's case (Fig. 4) shows the orifice of the sac in precisely the spot occupied by the fossa of Waldeyer. Brösike figures a case observed by himself in which the jejunum was adherent posteriorly. In order to clear up this point as to jejunal adhesion I have carefully examined the reports of all the cases recorded. In seven of them we may take it that this adhesion was present; in the remaining seven it was certainly absent. We may therefore describe two forms of right duodenal hernia, the former as hernia mesenterico-parietalis parajejunalis and the latter as hernia mesenterico-parietalis paraduodenalis. In both varieties the anterior margin of the sac contains the superior mesenteric artery. It is interesting to note that in two recorded cases, Zwaardemaker's and Neumann's, there was a twisting of the bowel at the orifice of the sac amounting, it is said, to volvulus.

FIG. 4.



Orifice of the sac of a right duodenal hernia. Dr. Barrs's case.

Diagnosis.—Duodenal hernia unless strangulated gives rise to practically no symptoms. In many cases the hernia has been found accidentally on post-mortem examination. When strangulation occurs in addition to the symptoms of acute intestinal obstruction a characteristic appearance of the abdomen has been noted. There is a tumour in the central part of the abdomen and around it a flattened area. The tumour has the following attributes. 1. It is limited to a definite region of the abdomen. In left duodenal hernia it lies at first to the left and upper, in right duodenal to the right and lower, parts of the abdomen, but in each case spreads eventually over almost the whole abdominal cavity. Around the tumour is an area of depression corresponding to the position of the colon. In size the tumour may vary. It has been described as being of the size "of a child's head." In Dr. Barrs's case it was "equal to a nine months' pregnancy." It is slightly moveable but is fixed during respiration. 2. The tumour is marked out distinctly by palpation. On percussion it is always resonant. The degree of resonance varies in different cases and in different parts of the same tumour. But the striking feature is that the tumour is a palpable, definite, resonant mass. In the centre of the tumour or over its whole mass may be seen coils of intestine. The tumour may bear a very obvious relation to the clinical condition of he patient, becoming more tense and prominent and very ch more tender when the symptoms undergo exacerbation. he symptoms decline the tumour becomes less aggres-fo- 3. On auscultation distinct gurgling sounds may be of c ywhere in the tumour.

portio portant to remember that owing to the position of The ori r mesenteric vein in the neck of a left duodenal sac the radicles of this vein may become enlarged, as in the case of the hæmorrhoidal veins, or venous trunks on the anterior abdominal wall may be so increased in size as to form a striking feature of the case.

LECTURE II.

Delivered on March 1st, 1899.

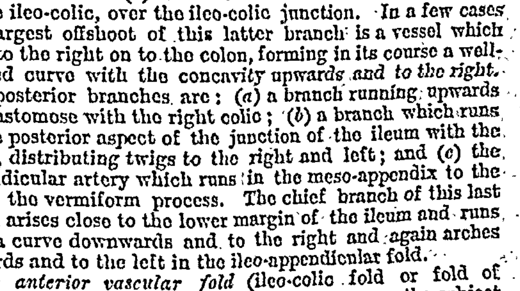
THE PERICÆCAL FOLDS AND FOSSÆ; PERICÆCAL HERNIA.

MR. PRESIDENT AND GENTLEMEN,—The pericæcal folds and fossæ are primary and secondary. The primary folds are vascular in origin; the secondary folds are dependent upon the adhesion, sometimes wanting, between the cæcum and ascending colon and the posterior abdominal wall. The primary folds are found whatever the position of the cæcum may be, the secondary are only present when the cæcum and ascending colon are normally placed. The primary folds are: (1) an anterior, raised up by a branch of the ileo-colic artery as it runs over the anterior aspect of the ileo-colic junction; (2) a posterior, raised up by the artery to the appendix; (3) an intermediate, which is partly muscular and partly vascular in origin; and (4) an accessory anterior fold due to a lateral branch of the ileo-colic artery.

The ileo-colic artery and its branches.—The ileo-colic artery as it approaches the angle of junction of the ileum with the ascending colon gives off as a rule five branches. The precise mode of origin of these branches may vary within considerable limits. The most frequent arrangement is for the vessel to divide into two main trunks which subsequently split up, the anterior into two and the posterior into three branches. The anterior branches are (*a*) a branch running to the left along the upper border of the ileum and (*b*) a branch which continues in the line of the ileo-colic, over the ileo-colic junction. In a few cases the largest offshoot of this latter branch is a vessel which runs to the right on to the colon, forming in its course a well-defined curve with the concavity upwards and to the right. The posterior branches are: (*a*) a branch running upwards to anastomose with the right colic; (*b*) a branch which runs to the posterior aspect of the junction of the ileum with the colon, distributing twigs to the right and left; and (*c*) the appendicular artery which runs in the meso-appendix to the tip of the vermiform process. The chief branch of this last vessel arises close to the lower margin of the ileum and runs with a curve downwards and to the right and again arches upwards and to the left in the ileo-appendicular fold.

The anterior vascular fold (ileo-colic fold or fold of Luschka).—This fold is constant. The younger the subject the better marked the fold as a rule. In the aged and in the obese it may become blurred and flattened, but is always present. It is semilunar in shape, having a curved attachment to the anterior layer of the mesentery, the anterior aspect of the ascending colon, and the cæcum down to the root of the appendix. The free edge of the fold containing the vessel looks to the left and is shorter than the attached margin, representing, as it were, the string of a bow. The fold is thin, sharp, and transparent in the young; thick, dull, and fatty in the aged. In its upper part are generally one or two small lymphatic glands. The ileo-colic fold is sometimes continued on into the appendix and the vessel it contains replaces the appendicular artery.

FIG. 5.



The ileo-appendicular fold and fossa and the meso-appendix.

The accessory anterior vascular fold —In 17 cases out of 200 I have met with a distinct fold raised up by the lateral branch of the anterior division of the ileo-colic before referred to A small fossa lies behind it Both the fold and the fossa determined by it have hitherto escaped recognition

The anterior vascular fossa (Ileo colic fossa; fossa of Luschka)—This is a narrow fossa or chink situated between the ileo-colic fold in front and the enteric mesentery, ileum, and a small portion of the upper and inner part of the cæcum behind

The posterior vascular fold, meso appendix (Fig 5) —To see this fold clearly the cæcum and appendix must be turned upwards It is quadrilateral in shape Its superior border springs from the mesentery; the right is attached to the colon on its postero internal aspect for a short distance and then to the cæcum; the inferior to the whole length of the vermiform appendix; the internal or left border is free and contains the appendicular artery The anterior surface is joined by—

The intermediate fold (Fig 5); *ileo appendicular fold* (Bloodless fold of Treves)—This is quadrilateral in outline The upper border is attached to the ileum, opposite the mesenteric attachment for about from one inch and a half to two inches and a half, the lower border extends from the angle formed by the appendix with the cæcum inwards on the anterior surface of the meso appendix, or occasionally on the appendix itself, the outer or right margin is attached to the inner aspect of the cæcum as far down as the root of the appendix, the left or inner border is concave and free This latter edge contains the recurrent, or ileo-appendicular, artery given off from the appendicular vessel close to the lower margin of the ileum Between the two layers of peritoneum in this fold especially in children, are seen some muscular bundles continuous on the one hand with the cæcum, and on the other with the ileum In later years so much fat may be deposited between the layers that it forms a solid slab resembling a miniature thickened omentum

The ileo appendicular fossa (ileo cæcal fossa) —This fossa lies between the ileo appendicular fold and the mesentery of the vermiform appendix On section it is triangular, being bounded above by the posterior surface of the ileum and the mesentery, in front and below by the ileo appendicular fold, and behind by the upper part of the meso-appendix Two cases are recorded in which it is believed that this fossa has become closed at its mouth and subsequently dilated to form a cyst (Schott, Widerhofer)

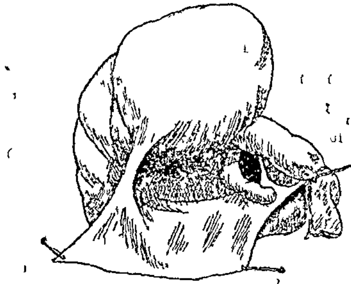
The fossa of Hartmann (fossa ileo cæcalis infima) —In some cases the lower attachment of the mesentery to the iliac fossa is prolonged into a sharp fold, the "inferior ligament" of Tuffier Between this fold and the vermiform appendix there may be found a small fossa, funnel shaped in general but occasionally sub-divided by a small peritoneal fold (Leichtenstern)

SECONDARY FOLDS AND FOSSÆ

On lifting up the cæcum there may be seen:—

The retro colic fossa (Fig 6) of variable size and capacity In some cases the whole length of the index finger can be comfortably laid in a sort of peritoneal tube which extends upwards to the kidney In others there may be merely a narrow and shallow dimple that would contain the tip of a lead pencil This fossa is bounded and determined by two folds—(1) an outer and upper and (2) a lower and inner

FIG 6



The retro-colic fossa

1 *The parieto colic fold* (fold of Hensing, superior ligament of the cæcum) —Roughly triangular in shape, this fold contains some tough, strong shining, fan shaped fibres Its posterior border is attached to the abdominal wall from the lower border of the kidney over the iliac crest of the iliac fossa; the anterior or internal border is attached to the postero external aspect of the colon, extending not seldom on to the cæcum also, the lower free border or base is concave and extends from the iliac fossa to the intestine The summit or apex is firmly fixed in the lumbar fossa

2 *The mesenterico parietal fold* (inferior ligament of Tuffier) —This is in reality the insertion of the enteric mesentery into the iliac fossa In some cases it is prolonged downwards as far as the inguinal canal in the plica genito-enterica of Treitz These two folds may be each continued downwards and may coalesce in the formation in the iliac fossa of a falciform fold In such a case the fossa formed by them would be retro-cæcal, not retro-colic

Fossa iliaco subfascialis (fossa of Biesiadecki) —This is situated about the middle of the iliac fossa, its orifice is directed upwards and is bounded in front by a more or less well defined fold, the inner extremity of which is directed upwards over the psoas towards the root of the mesentery and the outer extends towards the iliac crest The fossa is about from one and a half to two inches in diameter and is placed at the junction of the upper loose iliac fascia and the lower tense and more firmly fixed portion

Genesis of the folds —The ileo colic fold and the meso-appendix are vascular in origin The ileo appendicular fold is more difficult to account for Luschka believed that it was muscular in origin Treves asserted that it was the true mesentery of the appendix, the meso appendix being a substituted mesentery Jonnesco and Berry consider that the fold is a subsidiary mesentery of the cæcum Without entering into the reasons I may say that my view is that the fold is of dual origin, that it is primarily muscular, dependent upon the ileo-appendicular muscle and that later its development is modified by, and attributable to, the ileo appendicular vessel This fold is the last to appear in the embryo; it is less constant than the meso-appendix, and it receives its vessel (upon which it to some extent depends for its existence) from the posterior vascular fold

With regard to the genesis of the retro colic fossa and the parieto colic fold I have already stated that they are secondary and are due to the coalescence sometimes wanting, of the posterior surface of the ascending colon, and sometimes, though rarely, of the cæcum to the posterior wall of the abdomen

PERICÆCAL HERNIA.

So far as I am aware there are no cases on record which can be considered as hernial protrusions into either the anterior vascular fossa or the accessory anterior vascular fossa The fossæ are only of anatomical interest They have no pathology

With regard to the ileo appendicular fossa I have already referred to its cystic dilatation In four cases it has been the seat of a hernia

CASE 1 —This case was recorded by Tuffier in a meagre and unsatisfactory manner The patient was a man, aged 50 years who was very stout An intestinal loop which measured eight centimetres was contained in this pouch which was very dilated

CASE 2 —The specimen is in the Musée Dupuytren (*pièce de Michon*) This is referred to by Tuffier as a true specimen of ileo appendicular hernia Jonnesco says of it that it is not very convincing'

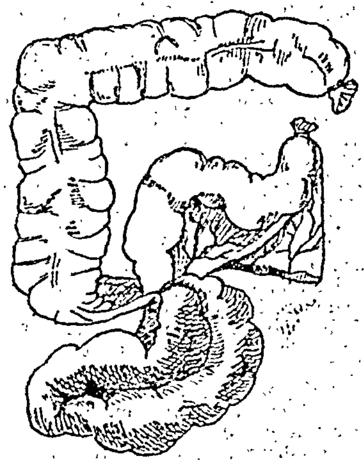
CASE 3 —This case was recorded by Dr Little, Fig 7 shows the condition The patient was a man, aged 60 years, powerfully built For nine days there were symptoms of intestinal obstruction, terminating fatally "From a point near the tip of the vermiform appendix a narrow but strong whitish band is seen passing to an attachment into the front of the ileum, at a distance of about two inches from the termination of the latter gut" A large loop (16 or 18 inches in length) was strangled by this band which is evidently the ileo-appendicular fold The case is very fully and graphically described and remarks are made on the anatomy of this region

CASE 4 —This case was recorded by Mr Partridge A maid servant, aged 26 years, died after five days acute obstruction. A knuckle of the ileum immediately above its termination was found to be strangulated and much congested in consequence of having passed through, and become impacted in, a hole or interspace in the mesentery of the vermiform appendix. The specimen is said to be in the King's College Hospital Anatomical Museum, but it cannot be traced.

There are also many cases of hernia of the vermiform appendix into the pouch.

Hernia into the retro-colic fossa.—Jonnesco accepts the following as genuine cases of hernia into this fossa: one by Fages; one by Wagner; one by Parise; three by Rieux; one by Engel; one by Klebs; one by Moxon; one by Josse; and one by Furst. On careful perusal of these cases the only ones which can be accepted as being even possibly of this class are the last two recorded by Rieux. All the others are negatived either by paucity and inexactness of description, or they belong quite obviously to a different variety altogether. Moxon's case, recorded by Pye-Smith, is in the Guy's Hospital Museum. It is a beautiful example of right duodenal hernia and has no connexion whatever with the cæcum.

FIG. 7.



Dr. Little's case of ileo-appendicular hernia.

Hernia into the fossa of Biesiadecki.—One example of this was exhibited at the Pathological Society of London by Dr. Mott. It was seen and recognised by Mr. Treves as a hernia into the fossa iliaco-subfascialis. A case recorded by Engel is very probably also of this variety.

Hernia into the fossa of Hartmann.—One case has been recorded by Dr. Snow. A woman, aged 24 years, when in the eighth month of pregnancy was seized with acute abdominal pain which was followed by symptoms of intestinal obstruction, ending fatally on the fourth day. The record of the post-mortem appearances is rather bewildering. I think, however, that only one conclusion is possible and it is that the hernia occurred into the fossa of Hartmann. The case is so accepted by Leichtenstern.

ON THE USE OF DIPHTHERIA ANTITOXIN IN GENERAL PRACTICE,

WITH THE RESULTS OF THE TREATMENT OF 122 CASES OF DIPHTHERIA.

BY J. RICHARDSON ARMSTRONG, M.D., M.S. EDIN.,
SURGEON TO THE PARC AND DARE COLLIERIES, TREORKY, SOUTH WALES.

IT is now generally recognised by the medical profession that the treatment of diphtheria by the injection of antitoxic serum gives far better results than any other treatment and lowers the mortality of the disease in a very marked manner. Antitoxin is now extensively employed in all our large hospitals with a diminishing death-rate, yet judging by the mortality from diphtheria in our large towns and popular centres I cannot help coming to the conclusion that the general practitioner does not employ it as often as he ought and that some do not employ it at all. This has led me to hope that my own experience in the treatment of over 120 cases occurring in my own practice during the last 18 months may prove interesting to brother practitioners and may induce some who have not yet given antitoxin much of a trial to do so at the earliest opportunity, and the result will, I am sure, be a diminished mortality from diphtheria in their own practices.

Up to June, 1897, I had no opportunity personally of judging of the value of antitoxin in the treatment of diphtheria, but during that month and the following months of 1897 an epidemic of that disease occurred in my practice, and I was able to form my own opinion of the value of antitoxin and to watch cases going on side by side, the severe cases being invariably injected by me and the mild cases being treated by the internal administration of perchloride of iron combined with acetate of ammonia (10 minims of the solution of perchloride of iron and one drachm of the solution of acetate of ammonia to half an ounce of water, to be taken every four hours for a boy of 16 years, dose in proportion to age). From June 27th up to Dec. 17th, 1897, I treated in all 42 cases of diphtheria. Of these I injected 22 cases, and did not inject 20, and there occurred six deaths. A glance at the subjoined table will show the relative proportion of deaths in the injected and non-injected cases:—

—	—	Recovered.	Died.	Mortality per cent.
Total number of cases treated from June 27th to Dec. 17th, 1897	42	36	6	$14\frac{2}{7}$
Severe cases and therefore injected with antitoxin serum	22	20	2	9
Mild cases (apparently) and therefore not injected	20	16	4	20

This table shows a total mortality of $14\frac{2}{7}$ per cent. with a 9 per cent. mortality for the more severe and injected cases and a mortality of 20 per cent. for the more mild and non-injected cases. This table in itself shows the value of antitoxin by the lower mortality of the cases in which it was used and when it is borne in mind that the injected cases were by far the worst cases it is evident that the saving of life must have been very considerable.

TYPES OF CASES INJECTED.

CASE 1.—The patient was a female, aged 19 years, who was first seen on July 18th, 1897, at 9 P.M., and who had a suspicious throat. On the 19th at 11.30 A.M. there were three distinct patches on the left tonsil and two on the right. The temperature was 98° F.; the pulse was feeble. 1500 units of antitoxic serum were injected. On the 20th, 24 hours after the injection, there were no patches at all and the patient felt much better. She made a rapid recovery. This case was seen during the first 24 hours of the disease; injection was early resorted to and hence the membrane disappeared early. The diagnosis was confirmed by subsequent bacteriological examination.

CASE 2.—A male, aged 20 years, was first seen at 4 P.M. on June 26th, 1897. There were suspicious but distinct patches on both tonsils which were enlarged. The temperature was 100·5° F. At 9 P.M. on the same day the patches were quite distinct and were larger and the temperature was 101°. 1500 units of antitoxin were injected. On the 27th at 9 A.M. (12 hours after the injection) the temperature was 101°, one patch was smaller, and a new patch was to be seen growing. At 9 P.M. (24 hours after the injection) the temperature was 103° and the patches were more distinct and were larger, but the patient expressed himself as feeling better. On the 28th, at 9.30 A.M. (36 hours after the injection), there was a speck of membrane at one spot in his throat and all the other patches were gone. The tonsils were red. The temperature was 98·7°. In the evening of the same day (48 hours after the injection) there was not a speck in the throat and the temperature was normal. On the 30th the tonsils were still enlarged but otherwise normal. On July 4th the tonsils were of normal size. This case was seen on the second day of the disease when the antitoxin was injected and the membrane had gone within 48 hours of the injection. The temperature went up during the first 24 hours after the injection, afterwards lowering.

SE 3.—The patient, a female, aged 13 years, was seen June 30th, 1897, at 1.30 P.M. The temperature was F. and the pulse was 120 and weak. Three well-defined wish-grey patches presented on the left tonsil and there three smaller ones on the right tonsil. Both tonsils enlarged and painful. The patient was hoarse. At M. I injected antitoxin. The patient was worse. At P.M., eight hours after the injection, the tonsils were ger and more swollen; the patches on the left were much ger and dirtier and on the right they were also confluent. e temperature was 102° and the pulse was 120. The lent was rather hoarser and her breathing was short. On y 1st, at 9.30 A.M. (18 hours after the injection), the temperature was 99°. The patches were to be seen dissolving; y were thinner and smaller, especially at the margins, d only two were left *on the left tonsil*, the right tonsil ing clear. The patient was not so hoarse. At 10 P.M. e was much better. The temperature was 99°. Two small tches on the left tonsil only remained. On the 2nd at 30 A.M. (40 hours after the injection) there was only a very nall patch on the left tonsil and at 10 P.M. (a little over *3 hours after the injection) there were no patches at all.* n the 4th the patient got up out of bed and she did well. he was a very delicate girl and she had suffered from hronic enlargement of the tonsils for years. The diagnosis as confirmed by bacteriological examination.

CASE 4.—The patient in this case was a female child, ged four years. I injected antitoxin on the third day of er illness. Both tonsils were covered with membrane, the reathing was rapid and stertorous, and the larynx was also ffected. Distinct improvement took place within 24 hours of the injection although the case was a very bad one, and the patient continued to make rapid progress. The throat and larynx were clear within 60 hours of the injection, and on paying my visit on the fourth day I found the patient downstairs and apparently quite well though a little feeble. She made an uninterrupted recovery.

CASE 5.—The patient, a female child, aged three years, was very hoarse when first seen. The tonsils were enlarged and membrane was filling the throat. The breathing was very laboured, stridulous, and rapid. The patient seemed quite "choked-up." The pulse was very rapid. I injected antitoxic serum at once, it being the third or fourth day of the illness. She remained very ill and in great danger for 24 hours and then she made a rapid recovery. The throat was quite free from membrane within three days of the injection. She developed post-diphtheritic paralysis which persisted for a few months but which eventually disappeared and left her quite as well as before the illness. From the history this appeared to be a case which was primarily laryngeal and secondarily pharyngeal.

CASE 6.—This was a very bad case. The patient was a male, aged nine years. When first seen his breathing was very short. There was a large patch about three-quarters of an inch in diameter on the soft and hard palates following large patches on the tonsils. After the injection of antitoxin rapid recovery took place.

CASE 7.—A male child, aged two and a quarter years, was taken ill on Dec. 7th, 1897, and was supposed to be suffering from a bad cold. On Dec. 10th I was sent for. On that day at noon I examined the child and found an enlargement of the glands at the angle of the jaw and a swelling of the neck. The breathing was short, stertorous, and croupy. On examining the throat internally I found extensive membrane on both tonsils and filling up the throat. I injected antitoxin at 6 P.M. (the fourth day of illness) when he was breathing with difficulty and his pulse was very rapid and feeble. He had a very restless night. On the 11th the throat was still full of membrane, which, however, showed a tendency to separate (less than 24 hours after the injection). On the 12th there was improvement in the patient's condition and on the 13th he was much better. The membrane was disappearing, some being left on one side of the throat only. On the 14th (less than four days after the injection) there was no membrane. On the 15th the child appeared very well. There was a much stronger pulse. The patient developed post-diphtheritic paralysis, but eventually he got all right after a few months. This was a very bad case. The antitoxin was not injected until the fourth day of the illness and yet the patient did very well.

TYPES OF CASES NOT INJECTED.

CASE 1.—The patient was a male, aged 13 years. There were patches on one tonsil. This was a mild case. I prescribed seven minims of the solution of perchloride of iron and 30 minims of the solution of acetate of ammonia to half an ounce of water every four hours. The throat cleared in *from three to four days.*

CASE 2.—A male, aged 11 years, was taken ill on Sept. 24th, 1897. He was seen by me on Sept. 26th, when I *found a fair pulse, patches on the tonsils*, and the general condition pretty good. I did not think him ill enough to order an injection and therefore ordered perchloride of iron and acetate of ammonia and brandy. On the 27th the patches in the throat were larger and the pulse was not so good. On the 28th there were large new patches, the pulse was feeble, and the heart was inclined to be weak. On the 29th the patches were beginning to grow smaller. They were still present on the 30th and there was a fresh one on the uvula. The general condition of the patient was not so *satisfactory as one* would wish. On Oct. 1st there were two patches on the uvula. The patches on the tonsil were thinner. The heart was slow and weak. On the 3rd the patches had nearly gone but there was *a trace on the right* tonsil. The patient's general condition was improving. On the 4th the patches had disappeared and improvement was *still going on.*

This case which equalled in its severity at the onset some of the very mildest cases injected does not compare favourably in its clinical history with the more severe injected cases. The patches, instead of clearing up in two or three days at farthest, as would probably happen with antitoxin, took seven days to disappear and they spread on to the uvula in addition and the condition of the patient was also critical for a few days from weak and slow heart.

CASE 3.—The patient in this case was a female, aged four years. When I saw her on Sept. 27th, 1897, there were small patches on the tonsils. I ordered perchloride of iron and acetate of ammonia and brandy every four hours. This was an apparently mild case. On the 28th and 29th the patches were larger and the pulse was feeble. On the 30th the throat was much the same, but the patient was better in herself—her general condition had improved a little. On Oct. 4th the patches still persisted and the patient was much the same. On the 5th the patches had nearly gone and there was slight improvement. On the 6th the patches had disappeared and the patient was all right.

The patches took nine days to clear up and the patient was in a feeble condition throughout, giving me more anxiety for a time than the very bad injected cases had done.

CASE 4.—The patient was a male, aged 18 years, who was seen by me on Sept. 29th, 1897. There was a patch in the throat. I ordered the mixture as in the previous cases. On the 30th there were a few patches. On Oct. 1st the patches were much the same, on the 2nd they were not so large, on the 3rd they were fading, and on the 4th they had gone.

In this case, which was a very mild one in an adult, it took five days for the patches to disappear.

CASE 5.—The patient was a male, aged five years. On Oct. 6th, 1897, the throat was inflamed, but there were no patches. I ordered the same mixture as in the previous cases. On the 7th there were well-marked patches on both tonsils and the breathing was rapid and feverish. On the 8th the patches were well marked and the heart was weak. He recovered slowly and gave me much anxiety owing to his heart becoming very feeble, and there were still thin patches on the pillars of the fauces on Oct. 14th, eight days from the onset of the illness and from the time when treatment commenced. He eventually got all right.

NOTES OF ALL THE FATAL CASES.

Fatal cases injected.

CASE 1.—I was called to see the patient, a female, aged two years, at 5.30 P.M. on June 30th, 1897. The pulse was rapid and the temperature was 98° F. The breathing was croupy, respiration was very rapid and difficult, the throat was a good deal swollen externally, and there were enlarged glands. On examining the throat internally I found it to be full of yellowish-grey patches scattered over both tonsils which were also enlarged. The larynx was evidently primarily badly affected and the disease was now spreading to the throat (the patient had been ill for a few days). At 7 P.M. I injected 1500 units of antitoxin. At 10.30 P.M. she was more collapsed than she had been. The temperature was 97° and the breathing was very stertorous and difficult. On examining the throat I found the patches to be confluent and the throat to be simply full of dirty membrane and slough. The child was gasping and appeared to be almost dead. There was great sucking in of the intercostals. I injected 1500 units more of the antitoxin. On July 1st, at 1 P.M. (17 hours after the first injection) I found the child still alive. The throat was almost clear of membrane and the breathing was very much easier and slower but the child was sinking and almost dead from exhaustion and heart failure. The temperature was 100°.

In this case it was evident that I had been called in too late, yet though the case was so severe and the child was nearly dead when first seen she lived until the following day and died when the disease was practically gone, 17 hours after the first injection. I thought she would have died fully 12 hours sooner.

CASE 2.—A female child, aged 15 months, was seen by me on July 25th, 1897, and was found to be suffering from a very bad attack of membranous croup. To all appearances she was dying. There was great sucking in of the intercostals in respiration. I injected antitoxin. On the 26th the breathing was better, but the child was very weak and collapsed and eventually she died of collapse and exhaustion 24 hours after the injection.

It will be noticed that in this case the patient lived for 24 hours after the injection of the antitoxin.

Fatal cases not injected (practically).

I look upon the following four cases as not injected, as they were treated with the solution of perchloride of iron and the solution of acetate of ammonia for several days and then injected when too late to be of value.

CASE 1.—I was called in to see a male child, aged four years, who was known to have been suffering from diphtheria for five days at least and after he had been treated with local applications to the throat and the solution of perchloride of iron internally. I found large dirty-greyish patches on both tonsils; they were distinctly membranous. I ordered the solution of perchloride of iron and the solution of acetate of ammonia and brandy internally. The pulse was feeble. On the following day more membrane was discovered in the throat and the pulse was weak. On the eighth day of illness (the third day of my attendance) the membrane was still there and the patient was getting much weaker. I injected 1500 units of antitoxin. On the ninth day the throat showed improvement, but the patient had developed passive congestion of the lungs. On the tenth day he sat up in bed at about 3 A.M. and fell back dead.

This was a case to which I was called not sooner than the sixth day of the disease. As the patient had already been attended by a medical man I unfortunately did not inject antitoxin when called in but left him for two more days without injection. It was quite impossible to keep this patient in bed and whenever I called to see him he was always dressed and lying on the sofa or sitting or walking. His parents did not seem to realise that there was much danger although I impressed it on them daily. If the antitoxin had been injected a few days earlier I believe he would have recovered.

CASE 2.—The patient was a male, aged four years, who was just recovering from scarlet fever. He was first seen on Sept. 21st, 1897. There were two large patches on the tonsils. I suspected diphtheria and I put the patient on perchloride of iron and acetate of ammonia. On the 22nd he was seen by my assistant and was reported as being much better. When I next visited him (on the morning of the 24th) I found him *to be very ill indeed. The throat was* almost choked up with membrane and the neck was swollen; breathing was difficult and very short and rapid. The pulse was weak and irregular. I injected antitoxin (fifth day). He had a bad night. On the 25th he was rather better; the patches were disappearing and the breathing was easier. He got up out of bed to micturate and was taken suddenly worse. He died in the evening from heart failure—30 hours after the injection.

The fact of the patient having been left too long before the injection of the antitoxic serum may perhaps be held accountable for the fatal issue in this case.

CASE 3.—The patient, a male, aged three years, was first seen on Oct. 4th, 1897. The throat was inflamed and there was a patch. The mixture and the brandy were ordered as in the former cases. On the 5th there were well-marked patches and the patient was feverish. On the 6th he was worse and the patches were larger. On the 7th the patches were fading anteriorly in the throat but they were still well marked posteriorly. On the 8th he appeared to be better but still there were patches present. On the morning of the 9th he was better. At 7 P.M. the breathing was noticed to be difficult and croupy and he became more restless and got gradually worse until I was sent for at 7 A.M. on the 10th. I found that the membrane had extended into the larynx and I injected antitoxin, but he got gradually worse and died 24 hours afterwards from asphyxia and exhaustion.

On Oct. 7th, 8th, and 9th the patient had appeared much better and had cried the greater part of the time, wishing to get up. This was in the early stages of the illness. It was a comparatively mild case and the patient would, I feel certain, have recovered with the injection of antitoxin earlier.

CASE 4.—The patient was a female, aged one year and 11 months. On Oct. 4th, 1897, the throat was bad, there were patches, and the neck was swollen. On the 5th, there were well-defined patches on both tonsils, and on the next day they were more marked. On the 7th, large greyish yellow patches, were raised up on both tonsils. The pulse was rapid and weak. On the 8th the patient was very ill. The throat was full of membrane, extending to the larynx. On the 9th she seemed a little better; there was less membrane in the throat. On the 10th I was sent for at 5 A.M., when I found the breathing to be difficult and croupy. At 7 A.M. I injected antitoxin. She got gradually worse; stridor and difficulty of breathing set in, the larynx got choked up, and she died from asphyxia at noon. The throat was full of membrane up to the end.

This case did not seem to be a very severe one at the beginning, so I treated it with the mixture and the brandy as in the other cases, and injected antitoxin when too late (on the sixth or seventh day). If it had been injected earlier the patient would probably have done well.

A glance at the clinical history of the above types of injected and non-injected cases will show that the injected cases (although much more severe) did much better than the non-injected cases and that they recovered in a much shorter time and gave me much less anxiety. The throat cleared up in the injected cases on an average in less than half the time which it took to clear up in the non-injected, and I felt quite happy about the injected cases after the first 24 hours, as a rule, while I never knew what was going to happen to the non-injected cases often for more than a week. The four fatal non-injected cases quoted above show the dangers of leaving even a mild case for any length of time non-injected, and it was the history of these four cases that led me to use antitoxin more frequently and with much better results from that time up to the present. The average time for the membrane to disappear from the throat after injection was two and three-quarter days; in the non-injected cases it averaged five and two-third days from the commencement of the treatment. The disappearance of the membrane seemed in both classes to mark a distinct improvement in the patient's condition; in the injected cases the patient was practically convalescent then, while the weak heart caused anxiety for some time longer in the non-injected cases. In the former class the patients were generally going about during the second week, while in the latter it was often not until the third or fourth week. The great danger in the non-injected cases, however mild apparently, was the shaky and feeble heart. Very rarely was there this danger in the injected cases after the first day or two. As a matter of fact, I often found the latter going about against orders after the first two or three days and yet there were no bad effects. The subjoined table tabulates these points and shows at a glance the value of antitoxin:—

—	Severe cases injected.	Mild cases non-injected.
Disappearance of membrane averaged... ...	2¾ days.	5⅔ days.
Recovery...	1 to 2 weeks.	2 to 4 weeks.
General condition during attack	Good after the first day or two.	Unsatisfactory for a week or two.
Condition of the heart	Regular and satisfactory after the first few days.	Shaky and weak for over a week and unsatisfactory for a week or more longer.
How long confined to bed...	One week or so.	2 weeks or more.
Mortality	9 per cent.	22 per cent.

My experience in these 42 cases taught me the value of antitoxic serum in the treatment of diphtheria and taught me to inject it in all except the very mildest cases with a much lower death-rate than in these 1897 cases. A large number of these cases were examined bacteriologically for the diphtheria bacillus and it was found in nearly every case examined.

During 1898 from Jan. 1st to Dec. 31st I treated in my practice 80 cases of diphtheria, many of them of a very severe type and primarily laryngeal and the very worst forms of the disease, and I had only three deaths during that period, or a mortality of 3¾ per cent. Of these 80 cases I injected 55 and treated the other 25 with the solution of perchloride of iron and the solution of acetate of ammonia and brandy internally and did not inject the antitoxin—i.e., I injected 68¾ per cent of the cases. In two of the fatal cases the parents refused to have the antitoxin injected when I wished and advised it and although I warned them that their children would most likely die if they persisted in refusing an injection. After losing three or four days of valuable time they consented, but it was too late and the children died. In the third fatal case the boy was injected *once* and the case being a very bad one I advised a second injection which the parents refused to agree to and the patient died. I believe that he would have recovered with a second injection. Hence but for the ignorance and prejudice of the parents of these three children the mortality in 1898 would probably have been *nil*. As it was it was only 3¾ per cent., compared with 14¾ per cent. in 1897. These three deaths occurred in January, 1898, and from Jan. 26th to Dec. 31st of that year 72 consecutive cases were treated without a single fatality and I attribute this to the injection of antitoxin in a very large proportion of the cases. The subjoined table shows the proportion of cases injected:—

—	—	Re-covered	Died	Mortality.
Total number of cases treated from Jan. 1st to Dec. 31st, 1898	80	77	3	3¾ per cent.
Severe cases injected	55	54	1	Under 2 per cent.
Mild cases non injected	25	23	2	8 per cent.

I look upon the two who refused injection until too late as non-injected

In 1897 I injected 52 per cent. of all my cases, while in 1898 I injected 68¾ per cent. of my cases; hence the mortality in 1898 of 3¾ per cent. compared with 14¾ per cent. in 1897 Taking the whole of the cases treated from June, 1897, to Dec 31st, 1898, with and without antitoxin, there were 122 cases with nine deaths, or a mortality for the whole period of 7½ per cent.

On referring to the annual report of the medical officer of health for the Rhondda Valley for the year 1897 I find that during the year there were reported in that district 247 cases of diphtheria with 78 deaths, or a mortality of over 30 per cent. Dr. Louis Cobbett's paper in THE LANCET of Dec. 3rd, 1898, in comparing the mortality of London from diphtheria with that of Berlin gives the deaths in London in 1897 as 2328 out of a total of 13,192 cases reported, or a mortality of over 17½ per cent. A glance at these mortalities seems to me to have but one explanation—viz., that the general practitioners of the day do not employ antitoxin as often as they ought to do in the treatment of diphtheria and do not seem to recognise the value of the sovereign remedy which they have at their disposal.

In my cases I injected 1500 units of antitoxic serum (Burroughs, Wellcome & Co) under the skin of the abdomen and I always used the liquid, not the dried, serum. This I found generally enough to cure the patient and in only *five* cases out of the 77 injected was a second injection called for after an interval of from two to three days. If the patient does not show a marked tendency towards improvement within 24 hours of the first injection or if the membrane does not clear up by the third or fourth day a second injection is indicated

Nine of my cases developed post-diphtheritic paralysis and one of them, a very delicate child, developed pneumonia about the ninth week and died. I have not seen any bad effects follow the use of antitoxin Rashes occurred in some of the cases—in one instance typically scarlatinal and accompanied by acute pains in the joints with tenderness and an elevation of temperature. This occurred about 10 days after the injection of the antitoxin and passed off in a couple of days. I also noticed the elevation of the temperature during the first twenty-four hours after injection, and after that a distinct lowering and the patients nearly always expressed themselves as feeling better within 12 hours of the injection.

The question may be asked, Ought antitoxin to be injected in every case of diphtheria? Some of the cases are sufficiently mild, in my opinion, to recover without it, so I will not go so far as to say that it is absolutely essential to inject in every case, although I would call it an excellent practice to do so and the patients would make much more rapid recoveries. I think that in every case, however mild, the patient ought to have the option of an injection and that injection ought to be insisted upon as early as possible in every case that is at all severe or likely to prove so and I think that the medical man who does not employ antitoxin and who loses a large proportion of his cases is incurring a responsibility which is almost criminal. The earlier a patient is injected the greater is the chance of recovery and the more rapid is the recovery.

Forty of the 1898 cases occurred in a branch practice and my success in their treatment is due in a great measure to the careful diagnosis and help rendered by my branch assistant, Mr. J. W. Collingwood Barrett. I might add that I invariably kept my patients on perchloride of iron and acetate of ammonia and brandy administered internally in addition to injecting them.

Treorky, South Wales.

OBSERVATIONS ON THE CEREBRO-SPINAL FLUID IN THE HUMAN SUBJECT.[1]

By STCLAIR THOMSON, M.D. LOND.,
PHYSICIAN TO THE THROAT HOSPITAL, GOLDEN-SQUARE, AND SURGEON TO THE ROYAL EAR HOSPITAL,

LEONARD HILL, M.B. LOND.,
LECTURER ON PHYSIOLOGY AT THE LONDON HOSPITAL MEDICAL SCHOOL,

AND

W. D. HALLIBURTON, M.D. LOND., F.R.S.,
PROFESSOR OF PHYSIOLOGY AT KING'S COLLEGE, LONDON

ONE of us (Dr. StClair Thomson) has had under his care for some years a young woman who has suffered from continuous dripping from the nose. The case has not been amenable to any treatment. At first it was thought to be one of nasal hydrorrhœa but certain characters in the affection convinced the observer that this could not be so and that the fluid (which dropped from one nostril only) was cerebro-spinal fluid. This was supported by the results of the chemical examination of the fluid. The escape of cerebro-spinal fluid from the nose has long been known to follow traumatic injury to the cribriform plate of the ethmoid bone, but the possibility of its spontaneous escape from the nose does not appear to have been fully established before the present instance. However, considerable research into the literature of the subject has shown that there are several cases recorded in which, though no history of injury existed, the flow of fluid from the nose was of such a character that they must have been similar to the present case, although in the majority of instances the true nature of the fluid escaped observation.

Many of these patients exhibited cerebral symptoms in the course of the disease, and some ultimately died from inflammation of the cerebral meninges, which had probably spread from the nose through some opening in the bony lamina that normally separates the cranial and nasal cavities. The full clinical details of this rare case and of the similar ones just referred to are, however, reserved for publication elsewhere The present paper is concerned only with the composition of the fluid and the variations it presents under different circumstances

Characters of the Fluid.

Our opportunities for examining the fluid chemically have been fairly frequent. The fluid was always collected in sterilised glass vessels and the examination was made as soon as possible by one of us (Dr. W. D. Halliburton) at King's College, London. The fluid is perfectly clear and colourless, looking like water; its reaction is faintly alkaline; its specific gravity is about 1005. On microscopic examination it shows no cells or other deposit. It gives no precipitate with acetic acid. It contains a trace of proteid, coagulable by heat, but the quantity is too small to give more than an opalescence. In another portion of the fluid it was ascertained that this proteid is precipitable by saturation with magnesium sulphate; it is therefore a globulin. Albumin and other proteids are absent. The fluid contains a substance which reduces Fehling's solution. A portion of the fluid was treated with excess of acidified alcohol; the proteid so precipitated was filtered off. The filtrate was evaporated to dryness over a water bath; the dry residue was taken up with alcohol, filtered, and again evaporated to dryness. Part was evaporated to dryness on a glass slide; the residue examined microscopically was seen to contain the needle-like crystals, occurring singly and in bundles, similar to those previously described and figured by one of us (Dr. W. D. Halliburton)[2] as obtainable from cerebro-spinal fluid. The residue had also the characteristic pungent taste of pyrocatechin. The remainder of the dry residue was dissolved in water and filtered. The filtrate reduces Fehling's solution well, but it does not ferment with yeast nor does it give any osazone crystals on treatment with phenylhydrazine hydrochloride and sodium acetate. Control experiments with a weak solution of dextrose, which gave about the same amount of reduction with Fehling's solution, gave both these tests in a typical way. The fluid was tested for creatinine with negative results.

---

[1] A paper read before the Roy... Fibros... Brit. Med. Jour., p. 314, where an illustration is

The same results relative to the reducing substance have been obtained over and over again in various specimens of this fluid. They agree with the observations of nearly all writers on the cerebro-spinal fluid, but differ from those of Nawratski[3] who in a recent paper has affirmed, principally from observations on the cerebro-spinal fluid of the calf, that the reducing substance present is dextrose.

The principal points to be noticed in the properties of the fluid which lead to the conclusion that it is cerebro-spinal fluid are the following: (1) its clear, watery character; (2) its low specific gravity; (3) the small amount of proteid in it and the absence of albumin; and (4) the presence in it of a substance which reduces Fehling's solution, but is not dextrose—it is possibly a substance related to pyrocatechin. In comparison with this fluid we examined also the secretion in some cases of true nasal hydrorrhœa. This fluid is opalescent, somewhat viscid, and on microscopic examination shows amorphous matter with mucous corpuscles. It gives with acetic acid a precipitate of mucinoid nature. It sometimes does and sometimes does not contain a reducing substance, and this substance when present is sugar. A quantitative analysis of one of these nasal fluids showed that the percentage of solids, especially organic solids, is higher than in cerebro-spinal fluid. The results of the analysis are as follows:—

Water	93·792	per cent.
Total solids	1·208	,,
Proteids (including mucin)	0·260	,,
Other organic substances	0·163	,,
Inorganic substances	0·785	,,

Our observations on the characters of the cerebro-spinal fluid were followed by others in which we sought to answer the following questions: the rate of flow; the difference of composition at different times of the day; the influence of straining, posture, and abdominal compression on the flow and composition of the fluid; and the effect on blood-pressure of intravenous injection of the fluid in animals.

The Rate of Flow.

One portion, collected by the patient herself in the course of an hour, measured four cubic centimetres. Another portion, collected under the supervision of one of us (Dr. StClair Thomson) in 10 minutes, measured 3·9 cubic centimetres. If the first portion is taken as a measure of the rate of secretion the amount formed in the day will be 96 cubic centimetres. Taking, however, the second observation as being more accurate the amount formed in the 24 hours will be over half a litre (561·6 cubic centimetres). It is possible that this estimate is too high, as doubtless the patient, being under the observation of a physician, would be somewhat

[illegible] consequent alteration of the circulation

9th he was [illegible]

would, as we shall immediately see, cause the flow to become more abundant.

Comparison of the Morning and Evening Fluid.

Cavazzani,[4] from experiments on dogs, found that the cerebro-spinal fluid collected in the morning was more alkaline than that collected in the evening and that it contained more solid residue. He considered that this was related to the activity of the nervous system and that it confirmed Obersteiner's theory of sleep. He obtained corresponding results in the case of a man with traumatic fistula of the frontal bone. We considered it worth while to repeat this observation. The qualitative examination of the fluid collected the first thing on several mornings gave the same results as that of specimens collected the last thing in the evening. Both were distinctly alkaline but no estimation of the relative alkalinity was made. The following table gives in percentages the results of the quantitative analyses:—

	Morning fluid.	Evening fluid.
Water...	99·004	99·027
Solids...	0·996	0·973
Organic solids	0·118	0·100
Inorganic solids	0·878	0·873

The evening fluid is thus slightly poorer in both classes of solid constituents than that of the morning; the difference is chiefly due to an alteration in the organic solids. This is just what we should expect, as the decreased capillary pressure during sleep would lessen the rate of exudation of water. Without committing ourselves to any theory on nervous activity or sleep we may say that our experiments confirm those of Cavazzani.

The Influence of Straining and Posture on the Flow and Composition of the Fluid.

In a monograph on the cerebral circulation[5] one of us (Dr. Leonard Hill) put forward the view that the rate of secretion of the cerebro-spinal fluid, when the cranio-vertebral cavity is opened, depends directly on the difference between the pressure in the cerebral capillaries and that of the atmosphere. At the same time it was shown that cerebral capillary pressure varies directly and absolutely with vena cava pressure. Thus the cerebral capillary pressure can be raised with great ease by any agency which causes a rise of pressure in the vena cava or cerebral veins. On the other hand, cerebral capillary pressure varies directly, but only proportionately, with aortic pressure, for between the aorta and the capillaries there lies the peripheral resistance.

It follows from the above that the easiest methods of raising the cerebral capillary pressure in man are: (*a*) by compression of the abdomen; (*b*) by the assumption of the horizontal posture (in this position, however, the rise of venous pressure may be compensated by the fall of arterial pressure which normally occurs when the body is at rest; this is, no doubt, the case during sleep); and (*c*) by straining or forced expiratory effort with the glottis closed. By all these methods the vena cava pressure is considerably raised; and by the last method the venous inlets into the thorax may be completely blocked and the pressure in the cerebral capillaries raised to something like aortic pressure. It is true that by such a forced expiratory effort the aortic pressure is lowered. Nevertheless, the total effect on capillary pressure is a very great rise, for a fall of aortic pressure of 25 millimetres of mercury produces a fall in cerebral capillary pressure of less than five millimetres of mercury, while a rise of vena cava pressure of 25 millimetres of mercury produces a rise of cerebral capillary pressure of 25 millimetres of mercury.

The present case gave us a unique opportunity of testing the correctness of these views on the living human subject and our experiments entirely confirm them. As will be seen from the following figures, the flow of cerebro-spinal fluid is accelerated by all those circumstances which raise the cerebral capillary pressure. The increase in flow is, moreover, *accompanied by a decrease in* the percentage of solid matter. The experiments were conducted under the supervision of two of us (Dr. StClair Thomson and Dr. Leonard Hill); the chemical investigation of the fluid was performed, as before, by the third (Dr. W. D. Halliburton). 1. The patient was sitting quietly without straining. In five minutes 23 minims (1·357 cubic centimetres) were collected. 2. The patient was sitting and straining. In five minutes 35 minims (1·965 cubic centimetres) were collected. 3. The patient was sitting quietly. In five successive minutes the amounts collected were respectively eight, seven, five, five, and five drops. The total measured 19 minims (1·021 cubic centimetres). 4. Subsequently to this five minutes were occupied by the patient in straining and the amounts collected in consecutive minutes were 12, 10, eight, nine, and 10 drops respectively. The total measured 33 minims (1·947 cubic centimetres). 5. The patient was lying down and not straining. The drops fell as follows in five consecutive minutes—nine, six, five, five, and five, and the total measured 27 minims (1·593 cubic centimetres). Here the arterial pressure was probably not decreased owing to mental excitement, while the cerebral venous pressure was increased. 6. The patient was lying flat on the stomach and the head was hanging over the end of a sofa. The drops fell as follows in five consecutive minutes—eight, seven, six, seven, and seven. The total measured 28 minims (1·652 cubic centimetres). 7. Finally, after the last experiment, the following was collected during quiet dropping while the patient was sitting with the head forward. The drops fell as follows—five, four, four, four, and four in five successive minutes, and the total measured 15 minims (0·885 cubic centimetres).

[5] The Physiology and Pathology of the Cerebral Circulation, by Leonard Hill. London: Churchill, 1896.

The following is the report on the chemical examination of the fluids. So far as the small quantities available admit of *analysis the fluids are the same qualitatively.* The liquid which escaped passively and that which passed under straining both contained a small quantity of organic and inorganic solids. Among the organic substances present are the reducing substance and a trace of proteid. Judged by the amount of precipitate produced by alcohol in equal amounts of the two fluids the proteid is less abundant in the fluid passed during straining, but the amount is too small to weigh.

Determination of the total solids gave the following results expressed in percentages: (*a*) the fluid passed passively, 1·1 per cent.; and (*b*) the fluid passed during straining, 0·43 per cent. Even the higher of these numbers is less than in cases of cerebro-spinal fluid from meningocele and hydrocephalus previously recorded by one of us (Dr. W. D. Halliburton.)[6]

In addition to the foregoing two specimens were collected at home by the patient herself. Analysis of these gave the following results:—*A.* Fluid collected while the patient was sitting upright quietly. The percentage of solids was 1·11. *B.* Fluid collected while the patient was lying down. The percentage of solids was 1·03. The effect of the horizontal posture is in the same direction, though not so marked as the effect of straining. This is what was to be expected, for the horizontal posture would not raise the venous, and thus the cerebral, capillary pressure so much as powerful expiratory efforts would. Moreover, the arterial pressure falls during quiet rest in the recumbent posture, as one of us (Dr. Leonard Hill) has determined.[7] In order to note the effects of straining on the retinal circulation Mr. Vernon Cargill was asked to examine the patient and he kindly reported as follows: "I noticed that when a straining effort was made a decided but transitory narrowing of the retinal arteries on and adjacent to the disc and also a marked pulsation in the trunks of the retinal veins occurred." The transitory narrowing of *the arteries points to the temporary lowering* of the aortic pressure, while the pulsation of the veins is a sign of the capillary engorgement due to venous congestion.

Experiments made with Abdominal Compression.

These experiments were made in order to complete and confirm those just recorded. The patient was seated and the abdomen was compressed as firmly and evenly as possible by one of us (Dr. StClair Thomson) spreading both hands over the front of the abdomen. The number of drops per minute were counted as before and periods of compression lasting five minutes were alternated with periods of the same duration, during which the patient was sitting quietly.

The following table gives the results succinctly:—

Condition of patient.	Drops in successive minutes	Total collected.	
		Minims	c.c.
A. Abdomen compressed ...	11, 9, 8, 7, 5	27	1·593
B. Sitting quietly	4, 5, 3, 4, 4	14	0·826
C. Abdomen compressed .	11, 8, 8, 6, 6	24	1·416
D. Sitting quietly	6, 7, 8, 6, 6	Measurement omitted.	

The fluids from experiments *A* and *C* were mixed together; also those from experiments *B* and *D.* Determination of the total solids gave the following results:—*A* and *C:* In fluid collected during abdominal compression the percentage of solids was 0·68. *B* and *D:* In fluid collected while the patient was *sitting upright quietly* the percentage of solids was 1·14. The experiments confirm those recorded in the preceding section. Abdominal compression raises the vena cava pressure and so leads to increased cerebral capillary pressure, and in this way to increase in the volume of the cerebro-spinal fluid secreted. Increase of volume, as before, is accompanied with fall in the percentage of solids present.

Intra-vascular Injection of the Cerebro-spinal Fluid.

One of us (Dr. W. D. Halliburton), in conjunction with *Dr. Mott, F.R.S.,* has been for some time engaged in examining the results of injecting into animals cerebro-spinal fluid removed from cases of brain atrophy, especially from cases of general paralysis of the insane. This fluid contains a toxic substance (choline), doubtless derived from the disintegration of lecithin in the brain. Injection of such fluid into the jugular vein of animals (dogs, cats, and rabbits) anæsthetised with ether causes a marked lowering of arterial blood-pressure which is partly cardiac in origin, but *principally due to the local action of the poison* on the neuro-muscular apparatus of the peripheral vessels, especially in the splanchnic area."[8] The fluid obtained from the present case was also injected in a similar way. Quantities varying from seven to 10 cubic centimetres were injected into the circulation in dogs but with entirely negative results. Such a quantity in the case of fluid from a general paralytic would be quite sufficient to cause a marked fall of arterial pressure. Similar negative results, both as regards blood-pressure and respiration, were obtained with other specimens of normal cerebro-spinal fluid removed from other animals or from cases of meningocele and hydrocephalus in children. In all such cases, also, choline was searched for chemically but with negative results.

ON ACUTE AFFECTIONS OF THE SKIN AND MUCOUS MEMBRANE OF THE MOUTH IN AN EARLY STAGE OF MYXŒDEMA;

PRIMULA OBCONICA AN ALLEGED EXCITING CAUSE IN ONE CASE.

BY ROBERT KIRK, M.D. EDIN., F.F.P.S GLASG.,
PHYSICIAN TO THE DISPENSARY FOR DISEASES OF WOMEN, GLASGOW WESTERN INFIRMARY.

As far as I am aware cases such as the two following have not hitherto been observed in connexion with myxœdema, the reason no doubt being that the early stages of this malady have generally been overlooked. Fortunately, the importance of its early diagnosis has lately been brought into deserved prominence by Dr. G. R. Murray.[1] An additional matter of interest in the cases here recorded will be found in the evidence apparently afforded by one of them of the great susceptibility on the part of a myxœdematous subject to the irritant action of the leaves of the primula obconica.
